COMPRESSED AIR may be used to operate a steam engine in lieu of steam without alteration if the exhaust ports are large. If they are not of good size they should be made so, or the escaping air will quickly cause the engine to "freeze up." This tendency may be reduced somewhat by discharging the exhaust under water, or better still, by reheating the air before sending it to the cylinder of the engine.

WHEN constructing a dam in a stream where it is not built securely on bedrock, it is very essential to provide against washing out of the base of the dam by the water flowing over the crest of the dam. In the construction of a large dam in San Diego county, Cal., the dam was built to such a height that the overflow passed over a low saddle between two adjacent hills on the bank of the artificial lake, so there was no possibility of the dam being undermined from overflow.

A MINING LOCATION may be made before a discovery has been made, but the actual existence of the claim will date from the discovery of the "mineral in place." Should a second party enter the claim so located and first discover mineral in place, the fact that the first party had already made a location without having a bona fide discovery will not save the claim to the first locator, as the discovery of mineral is the essential thing.

IN Alaska and the Klondike, where thawing of the ground is necessary in order to work the gold-bearing gravel, the difficulty arising from freezing of pipe connections when the steam was turned off was overcome by using graphite, which kept the pipes from rusting and making their disconnection convenient and easy. Graphite used on rubber gaskets where steam is used will always make it easy to remove the gasket when necessary, as it does not adhere to the pipe or boiler or other surface.

IN figuring the value of ores by assay, the commercial assay as ordinarily made is always meant, and not corrected assays. If the value of a shipment of ore is based on a corrected assay, where all losses by dusting, volatilization and absorption are taken into consideration, such computation will result in a misunderstanding with the ore buyers. The buyer's samples will not check with the seller's, and when the dispute is left to the umpire to make control assays the umpire's assays are more than likely to agree with those of the buyer than with those of the seller.

A MIXING oil cloth such as is commonly used in the assay office becomes a source of danger in creating inaccuracies in samples when the cloth becomes worn, having many cracks and small patches of enamel scaled off. Such a cloth should be thrown away, as it is no longer reliable. This is particularly the case where both high and low grade gold ores are being assayed. Where a low-grade sample follows a rich one there is great danger of salting the low-grade sample and too much pains and precautionary measures cannot be taken. Assays are useless unless they are accurate.

JIGS are of all sizes and shapes, from the small laboratory hand-operated machine to the large devices over 20 feet in length and 4 or 5 feet square. This latter size will handle 600 tons and over per twenty-four hours. Most jigs are provided with a piston which, operating vertically in the water compartment, transfers a pulsating motion to the water in adjoining screen compartments, and causes a grading of the mineral with regard to its specific gravity. The largest jigs are so arranged that the screens are operated directly by cam movements, and are also provided with side shaking device.

SECRETARY HITCHCOCK, Secretary of the Interior, recently decided that the work of prospecting a gravel claim with a drilling machine, by means of which bore holes are sunk at various points on the claim for the purpose of proving it, is an expense which may be properly charged to the annual assessment work required prior to patent. A reservoir and ditch built for the ultimate operation of a placer claim, are also properly chargeable to assessment work for the benefit of the claim. This decision was in the case of D. M. Vance v. T. L. and W. S. Adams at Jenny Lind, Calaveras county, Cal.

THE cost of smelting can only be estimated, even approximately, when the character of the ore to be treated is known; the proper fluxes required and their cost; the price of fuel and of labor, both skilled and unskilled, as well as size of plant. The region where the smelting is to be done is often an important factor. In some localities fuel is cheap, but fluxes are only obtainable at high cost; in others, the fluxes are at hand, but all fuel has to be shipped in. The size of the furnaces is important, as it is much cheaper to smelt in a large plant than in a small one. The cost of lead smelting under favorable conditions ranges from \$4.50 to \$7 per ton, and of copper from \$3.50 to \$8.

AN approximate computation of the capacity of an air compressor may be made by multiplying the area in square feet of the intake cylinder by twice the length of the stroke in feet, and this by the number of revolutions per minute when running at the usual speed, deduction being made for the piston area. This assumes that air is taken at each end of the cylinder. Of course this calculation is only approximate, due to slight imperfections of the valves, etc. If the valves do not close promptly at the proper time there is a loss of air. Valves which stick can often be successfully lubricated and kept in good condition by use of a little kerosene oil, applied with the usual machinery oil can.

THE Colorado State mining law contains the following: "All persons shall be prohibited from riding upon any

cage, skip or hucket loaded with tools, timber, powder or other material, except for the purpose of assisting in passing same through shaft or incline; and then only upon special signal." The law also requires all shafts to be divided into at least two compartments, one of which is for ladders, and in vertical shafts landings shall be constructed in the manway compartment not more than 20 feet apart, the landings to be covered except an opening large enough to permit the passage of a man, the ladders to be inclined at the most convenient angle the space available will allow. The ladders must be securely fastened and kept in good repair.

A NUMBER of ingenious devices are used to obtain samples from various depths in cyanide vats, particularly where slimes are being treated. It has been suggested that a bottle—similar to the laboratory distilled water bottle—be used for this purpose. The bottle, or jar, should be provided with a cork stopper through which passes two pipes, one extending nearly to the bottom of the bottle, the other being inserted only a short distance below the cork, and being, in fact, a vent. The other pipe is provided with a rubber hose of proper size weighted at its lower end, so that it may sink when lowered with the bottle into the pulp. The vent pipe extends upward from the top of the bottle as far as necessary to keep the upper end above the surface, and should be provided with a cock, to be kept closed when the bottle and hose are immersed until the desired depth has been reached, when it may be opened and the pulp will flow into the bottle, the air escaping through the vent. A device of this kind is useful to obtain samples of water from varying depths, and it may be found equally useful in securing pulp samples from variable depths.

THE group of elements known as the platinum metals are ruthenium, osmium, rhodium, iridium, palladium and platinum. Iron is also usually present. These several metals occur in nature nearly always as alloys, into the composition of which all of them usually enter. These metals do not occur abundantly, nor are they as widely disseminated as gold. Gold is usually associated with platinum, not always as an alloy, but accompanying it, due to the fact that gold veins occur usually in the same rocks as those which produce platinum, and both being of high specific gravity are found together in the placers. When gold occurs with platinum and the other metals it is recovered by dissolving the gold from the alloy. The process is based on the fact that gold is soluble in dilute aqua regia, while platinum is only soluble in concentrated aqua regia. Platonic chloride and iridium chloride form with ammonium chloride compounds which are soluble with difficulty. When the compounds are highly heated they are decomposed and the metals are left behind. When platinum-bearing sand has been recovered from sluices it is concentrated to get rid of the sand, etc., and the concentrate is boiled in dilute aqua regia, which dissolves out the gold. The residue is then boiled in concentrated aqua regia, which dissolves the platinum and usually also some iridium, leaving an alloy of iridium and osmium.

STRICTLY speaking, squatters, or other persons, have no right whatever on the mining ground located and properly held by others under the mineral land laws of the United States. In new mining camps where rich mines are being discovered and developed others than the claim owners usually rush in and pitch their tents on the first available spot regardless of ownership. This, under the laws, they have no right to do. Section 2322 of the Revised Statutes provides as follows: "Locators shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes or ledges, throughout their entire depth, the top, or apex, of which lies inside of such surface lines, etc." This section very clearly gives the locator exclusive dominion over the surface of his location, and it applies with equal force to placer or lode locations and millsites which have been properly located in accordance with the statutes, and this relation of the owner to the outsider obtains so long as the locator or his successor in right complies with all the requirements of the law. Although the law on this point is clear, it is sometimes expedient for the claim owner to make a concession whereby the surface of his claim may be used for the purposes of residence, or merchandising, etc., by others who have no interest whatever in the mineral rights. Convenience may require that city streets, as well as town lots, be staked out on the claims of the early prospectors. This procedure the claim owners may, at their option, obstruct, but it is usually the part of wisdom to permit the town to take a natural growth and to extend wherever circumstances dictate. To sell such rights may lead to cloud upon the mining title. At Tonopah, Nevada, the claim owners ceded their surface rights with certain reservations as a matter of expediency, and in order that there should be no adverse to the application for patent. The Supreme Court of the United States has decided that there can be no color of title in an occupant who does not hold under any instrument, preceeding or law purporting to transfer to him the title, or to give to him the right of possession. And there can be no such thing as good faith in an adverse holding, where the party knows that he has no title, and that under the law, which he is presumed to know, he can acquire none by his occupation.

## Mine Bell Signals.

TO THE EDITOR:—For the engineer, whose duties carry him to widely separated mining districts and perhaps States, the importance of adopting a uniform code of mine signals cannot be too strongly urged.

Of course a complete code of signals which would fulfil the want in one case could not be made applicable to all others, but there are a number of important signals, such as "hoist," "lower," and those required in handling men and in blasting, which are not affected by local conditions, and it is to these that reference is being made. It is almost generally understood in this country that the signal, 3 bells, means that men are to be hoisted. The writer has observed, in more than one instance, in the same district, the following signals employed for this purpose:

A mine, 3—1 bells. Hoist men.

B mine, 3 bells. Hoist men.

It can readily be seen what a dangerous practice it is to any one going from A to B mine, especially if not always accompanied by one familiar with the respective signals.

So it is with other signals, especially that used in blasting during shaft sinking.

In Mexico I think there is even greater carelessness in the use of mine signals than in this country. This is induced and, one might say, encouraged by the generally crude and slack methods attending the operations in a large number of cases.

In Johannesburg, Africa, a code of the important signals used in mining are embodied in the "Mining Regulations," and their use is rigidly enforced. I think it is generally acknowledged by men of African experience that the regulations covering the work of mining, as well as the use of boilers, are as comprehensive and complete as could be desired to meet the requirements of that country. The following quotations are taken from these regulations:

In signaling, the following shaft signals shall be used—  
1 bell, raise when engine is at rest.  
1 bell, stop when engine is in motion.  
2 bells, lower.  
3 bells, men about to ascend or descend.  
3 bells, in reply, men may enter the cage or other conveyance.  
5—2—1 bells, blasting signal.

In no case shall any person enter the cage or other conveyance until the back signal, 3 bells, has been given. The engine driver, when receiving the signal 1 bell or 2 bells (signifying to raise or lower any person), shall wait at least ten seconds before starting to wind.

The above code of signals, in the form of a distinctly legible notice painted on a board or enamelled plate, 22 inches high and 20 inches wide, shall be posted up in the engine room, at the top and bottom of the shaft, and at the intermediate shaft stations for the time being in use.

Special signals may be used at any mine, provided they are easily distinguishable by their sound or otherwise from the foregoing code, and do not interfere with it in any way.

In the above code the signal used in connection with hoisting men has been modified, and the return signal is no longer in use.

The blasting signal is applied as follows: When 5 bells are rung, the engine driver lifts the conveyance a distance of 10 feet, in order to see that the engine is at the time in working order. When the next 2 bells are given the skip or bucket is lowered to the bottom, then one bell is rung, to be hoisted away from danger.

The writer, some years ago, when on the executive of the Rhodesia Chamber of Mines, was called upon to investigate the question of mine signals then in use in that country with a view to recommending to the Government a code of signals to be embodied in the "Mineral Ordinance."

The result of this inquiry would have been ludicrous had it not disclosed such a dangerous state of affairs.

It was decided that the best course to pursue was to request each mine manager to furnish a code of signals which he considered would cover his requirements. From these contributions was compiled a code as simple and complete as possible—those signals which had to be adjusted to meet local conditions being left to the discretion of the individual managers.

In due course each manager was furnished with a printed code, accompanied with a request that they be immediately adopted and placed in the most conspicuous places.

In this country one is impressed with the importance of adopting some such similar action with regard to mine signals. It might also be advisable to consider the compilation of a mining ordinance, as well as boiler regulations, with a view to restricting operations to such an extent as to eliminate many of the risks attending gold mining as carried on at the present time.

In Africa, Australia and other countries mining inspectors are employed by the Government, whose duty it is to periodically visit the different mines in their respective districts and inspect the condition of the mines, as well as the surface equipment.

In our cities we have building inspectors and it appears to the writer that, in such an important mining country, the Government should offer some

assistance in the protection of those who are engaged in this latter industry.

F. C. ROBERTS.

Berkeley, Cal., May 2.

Realizing the importance of a uniform code of mine bell signals, the California Legislature adopted a code of bell signals several years ago, which is as follows:

1 bell, to hoist. (See Rule 2.)  
1 bell, to stop, if in motion.  
2 bells, to lower. (See Rule 2.)  
3 bells, man to be hoisted; run slow. (See Rule 2.)  
4 bells, start pump if not running, or stop pump if running.  
1—3 bells, start or stop air compressor.  
5 bells, send down tools. (See Rule 4.)  
6 bells, send down timbers. (See Rule 4.)  
7 bells, accident; move bucket or cage by verbal orders only.

1—4 bells, foreman wanted.  
2—1—1 bells, done hoisting until called.  
2—1—2 bells, done hoisting for the day.  
2—2—2 bells, change buckets from ore to water, or vice versa.

3—2—1 bells, ready to shoot in the shaft. (See Rule 3.)  
Engineer's signal that he is ready to hoist is to raise the bucket or cage 2 feet and lower it again. (See Rule 3.)  
Levels shall be designated and inserted in notice hereinafter mentioned. (See Rule 5.)

For the purpose of enforcing and properly understanding the above code of signals the following rules are hereby established:

RULE 1. In giving signals make strokes on bell at regular intervals. The bar (—) must take the same time as for one stroke of the bell, and no more. If timber, tools, the foreman, bucket, or cage are wanted to stop at any level in the mine, signal, by number of strokes on bell, the number of the level first before giving the signal for timber, tools, etc. Time between signals to be double bars (— —). Examples:  
6—5 would mean to stop at sixth level with tools.  
4—1—1—1—1 would mean to stop at fourth level, man on, hoist.

2—1—4 would mean stop at second level with foreman.

RULE 2. No person must get off or on the bucket or cage while the same is in motion. When men are to be hoisted, give the signal for men. Men must then get on the bucket or cage, then give the signal to hoist. Bell cord must be in reach of the men on bucket or cage at station.

RULE 3. After signal "Ready to shoot in shaft," engineer must give the signal when he is ready to hoist. Miners must then give the signal of "Men to be hoisted," then "spit fuse," get into the bucket, and give the signal to hoist.

RULE 4. All timber, tools, etc., "longer than the depth of the bucket," to be hoisted or lowered, must be securely lashed at the upper end to the cable. Miners must know they will ride up or down the shaft without catching on rocks or timbers and being thrown out.

RULE 5. The foreman will see that one printed sheet of these signals and rules for each level and one for the engine room are attached to a board not less than 12 inches wide by 36 inches long, and securely fasten the board up where signals can be easily read at the places above stated.

RULE 6. The above signals and rules must be obeyed. Any violation will be sufficient grounds for discharging the party or parties so doing. No person, company, corporation, or individual operating any mine within the State of California shall be responsible for accidents that may happen to men disobeying the above rules and signals. Said notice and rules shall be signed by the person or superintendent having charge of the mine, who shall designate the name of the corporation or owner of the mine.

Section 3 of the law says: "Any person or company failing to carry out any of the provisions of this Act shall be responsible for all damages arising to or incurred by any person working in said mine during the time of such failure."

The official code of Colorado is similar to that of California, but the several rules of that code differ slightly. For comparison the Colorado rules are given in full as follows:

Rule 1—In giving ordinary signals make strokes on bell at regular intervals. In signals similar to "Ready-to-Shoot" (3—2—1 bells), each bar (— —) must take the same time as each stroke of bell.

Rule 2—When men are to be hoisted or lowered, give the signal for "Men on, run slow" (3 bells). Men must then get on bucket or cage, then give signal to hoist, or lower (1 or 2 bells).

Rule 3—After signal "Ready to shoot" (3—2—1 bells), engineer must give signal that he is ready to hoist by raising and lowering bucket 2 feet. Miners must then give the signal "Men on" (3 bells), then "spit fuse," get on bucket or cage and give signal to hoist.

Rule 4—All timbers, tools, etc., "longer than the depth of bucket" or placed within a cage, must be securely lashed before being hoisted or lowered.

Rule 5—Signal of three (3) bells means "Men on, run slow," and nothing in conflict therewith will be allowed. Signals to meet local demands, and not in conflict with the above, may be added by individual operators, but the same must be posted in clear and legible form in connection with the above code.

### NOTICE.

Please observe the following, as they are imperative in order to comply with the law:

Don't get on bucket without first seeing that safety chain is properly hooked.

Don't get on cage or bucket without first signaling the engineer. Give 3 bells, then get on cage or bucket and ring 1 bell to hoist and 2 bells to lower.

Don't ride on loaded cage or bucket.

Don't ride on cage or bucket containing tools, timbers or explosives.

Don't load steel or timbers without first landing car or bucket.

Don't attempt to get on or off cage or bucket while in motion.

Don't leave guard rail thrown back.

Don't get in a hurry in signaling engineer; space your bells.

Don't work in ground you consider dangerous. Call your foreman's attention to the condition of the ground. Don't be careless, thereby endangering the lives of your fellow workmen.

Don't drill in an old hole or "gun."

Don't fail to thoroughly examine ground for missed shots before starting to drill, whether any misses are reported or not.

Don't attempt to pick out a missed shot.

Don't store explosives in excess of one day's supply under ground, but in magazine provided for that purpose.

Don't thaw powder except in powder trower, which must be provided for that purpose.

Don't use steel or a metal rod of any description for tamping.

More recently the Western Federation of Miners adopted a code which is in use in several localities, but that code, which follows, is not as good as that of either Colorado or California, as it appears to lack sufficient protection to the handling of men in the shaft. There is no signal to hoist or lower after the 3 bells are given. If men step on a skip or cage and merely ring these bells, they must depend on the engineer's judgment in giving them time to arrange themselves safely before starting.

The Western Federation code is as follows:

1 bell, hoist; 1 bell, stop (if in motion).  
2 bells, lower men; 3 bells, hoist men.  
4 bells, blasting signal. Engineer must answer by raising bucket or cage a few feet and letting it back slowly; then 1 bell, hoist men away from blast.  
5 bells, steam on; 6 bells, steam off.  
7 bells, air on; 8 bells, air off.  
3—2—2 bells, send down tools.  
9 bells, danger signal (fire, accident or other danger).  
Then ring number of station where danger exists.

No person shall ring any signal bell except the station tender, except in case of danger or when the main shaft is being sunk.

Engineers must slow up in passing stations when men are on the cage or bucket.

Here a lengthy combination of numbers is inserted indicating the several levels from the first to the twentieth.

If a cage is wanted, ring station. Station tender will respond in person.

If station is full of ore and station tender is wanted, ring station signal.

One copy of this code shall be posted on the gallows-frame and one before the engineer.

The first signal (one bell to hoist, or stop, if in motion) is in common use almost everywhere, and cannot be improved upon, but the signals "2 bells" lower men and "3 bells" hoist men are defective, as giving no premonitory warning, and make no distinction, so far as indicated by the published code, between men and materials. A better signal for lowering men is 3—2. This indicates that there are men to be lowered, whether it be from the surface or from some level to a level below it. If men wish to descend to any particular level, that level should be rung first, then 3—2. A hoisting signal for men, which has had years of trial is 3—1, or, hoisting with men from a level to any one above, the level first, then 3—1.

The clause requiring the engineer to slow up upon approaching each level seems superfluous and is prohibitory to rapid winding where large tonnage is hoisted daily through a single shaft, and would be unnecessary in a well-constructed shaft where there is competent and experienced management. The provision that the signal code shall be posted in the engine room and on the gallows-frame at the collar of the shaft should include the station at each level of the mine. It seems unfortunate that the signal code is not uniform throughout the United States, as then miners, who are migratory, would be familiar with it, no matter in what district they might be employed.

## Relation of Law to Underground Waters.

A report of great practical value, called "Relation of the Law to Underground Waters," by D. W. Johnson, has just been published by the United States Geological Survey as Water Supply and Irrigation Paper No. 122. It is the first comprehensive paper prepared in this country on the relation of the law to underground waters, and was compiled to meet a considerable demand for information on this subject. It is especially pertinent at this time, when active efforts are being made in several States to enact laws governing the use of underground waters which shall take account of the recent advances in the science of hydrology and the present knowledge of the occurrences and movements of such waters. The report is in no sense, however, a legal treatise, but rather the result of an endeavor to collect and arrange such legal decisions as will serve to show the relation of the law to problems which are essentially geological in character.

Mr. Johnson divides his discussion into two parts. In the first part he assembles the common-law rules

concerning underground waters; in the second he rehearses the legislative acts affecting underground waters. He divides underground waters into two classes, those flowing in defined and known channels, and those passing through the ground below the surface, either without definite channels or in courses which are unknown, and he arranges all the laws relating to underground waters under these two heads.

This report brings into striking relief the fact that there is a great lack of agreement among authorities on questions pertaining to underground waters. This is because there is so much that is uncertain and indefinite in the behavior of waters hidden beneath the surface. A second and very important reason for the unsatisfactory condition of the law relating to underground waters is found in the fact that the state of our knowledge regarding such water is now, thanks to the progress of geological science, in advance of the general ruling of the courts on some of the questions involved. Where a decision is controlled by opinions rendered in former cases, and not made with due regard to the present knowledge respecting subterranean conditions, it does not seem

### Concrete Mortar Blocks.

TO THE EDITOR:—In regard to your editorial on foundations for mortar blocks, I would suggest that anyone interested in the subject would be interested in examining the condition of the mortar blocks in the mill of the Royal Consolidated mines at Hodson, Calaveras county, Cal.

This mill of 120 stamps was built about two years ago and has cement foundations for the whole structure, including the crusher, line shafts, motors and mortars. The mortar blocks extend beyond the mortar front and back 12 inches. A rubber gasket is between the mortar and the cement.

The assistant manager, Mr. Unger, tells me no trouble whatever has been experienced with the cement mortar blocks, and moreover a personal examination showed them to be in perfect condition.

Owing to a number of breakages, the size of the cam shaft has been increased an inch (to 6½ inches).

The master mechanic has recently succeeded in welding the broken cam shafts and informs me that it pays. He has nothing extra in the blacksmith

\$10,000 to \$20,000 in a milling plant, it were best to spend a couple of hundred for a test to determine the character of the mill needed to crush the greatest amount of ore with the greatest saving, and if the cyanide process is necessary, the working details of it, so that instead of starting out blindfolded, as it were, one has some idea of how to work. I have no hesitation in saying that the additional saving in the first month in a mill which has had its ores tested by a competent man will more than pay the cost of such tests.

The general idea is only to get the mill up and the ore will do the rest; but often this is not so—the mill is put up, but perhaps is unsuited for the ore.

It is peculiar that the Easterners and often Californians, who would not think of putting up a factory except upon the most improved lines, will put up a ramshackle of a mill and expect dividends the first month. If it is lack of funds they had much better wait and put up a first-class mill, for otherwise they are courting failure. Nothing is too good for a stamp mill. Every piece of machinery or structure should be first-class; it means saving in repairs, and, what is as important, saving in time. All machinery

Concrete Mortar Blocks, Royal Con. Mill, Hodson, Cal.

that a just settlement of the controversy can be reached.

There probably must always be cases in which the subterranean conditions are indefinite or unknown, but the number of such cases will decrease with advance in geologic knowledge. The lack of agreement among legal authorities on many of the questions at issue is rather more fortunate than unfortunate in one respect at least, since it bears witness to the uncertain position of the law on the points involved and opens the way more readily for new knowledge concerning the problems, and a wiser interpretation of the law.

Mr. Johnson's paper is published for free distribution and may be obtained on application to the Director of the United States Geological Survey, Washington, D. C. It will prove of interest to mine owners who are developing water supply by means of wells and underground excavations.

ELECTRICITY is not a form of energy, any more than water is a form of energy, says Sir Oliver Lodge. Water may be a vehicle of energy when at a high level or in motion; so may electricity. Electricity cannot be manufactured, as heat can; it can only be moved from place to place, like water, and its energy must be in the form of motion or of strain. Electricity under strain constitutes charge; electricity in motion constitutes a current and magnetism; electricity in vibration constitutes light.

IN order to meet the cost of production, it has been found necessary to advance the wholesale price of the topographic maps published by the United States Geological Survey. Instead of costing \$2, the present price, 100 standard topographic atlas sheets will cost \$3 after June 30. The retail price of these maps will continue to be 5 cents a copy.

shop in the way of equipment, but makes an ordinary butt weld.

MARK R. LAMB.

San Francisco, Cal., May 8.

### Milling Gold Ores.

Written for the MINING AND SCIENTIFIC PRESS by  
ALGERNON DEL MAR.

The tendency of the times is toward fast crushing with often a consequent loss in the tailings, this loss being taken care of by a cyanide plant. So much is this the case that a word of warning may not go amiss. The cyanide plant is often not thought of until the results of fast crushing and poor amalgamation clearly shows the loss, often enough to cause a failure and the shutting down of the mill, for the cause is not perhaps apparent. It is now that the cyanide plant is rushed into place as a sure cure for all evils, often without any previous experimenting as to its fitness or its details, or if a cyanide plant does not appeal to the management a different style of crushing plant may be installed.

Fast crushing is all right in its place and where needed, but one must remember that the saving of the gold at lowest cost is important. There are some mines with practically an unlimited supply of low-grade ore which must be crushed as quickly as possible and where a loss of 25 or 50 cents a ton is compensated for by the increased tonnage. To this class of property triple discharge mortars, heavy stamps, low discharge and coarse screens are often undoubtedly the correct thing, but these mines are "few and far between." The great majority of mines now being opened are mines with a small ore body exposed and which must make a good showing from the beginning. Now, surely, before investing

should be purchased not for its cheapness, but for its fitness. There is nothing in continually hanging up a mill on account of defective machinery or running at a reduced speed on account of poor foundations. Have everything first-class from battery blocks to breakers, and don't forget the comfort of the amalgamators. They are human and don't like draughty buildings any more than the superintendent does; they do not yearn to be frozen in winter nor cooked in summer. The company that takes interest in the comfort of the millman will get a big return in extra care and attention which he will be able to bestow upon the machinery and the saving of the yellow metal. Take one small item for instance, that of keeping the cam shaft and the cams greased. There is a difference of about 3% to 4% in power from a well-attended cam shaft and a neglected one, not counting repairs caused by negligence. Now, in a cold, draughty mill, there is little inducement to leave the fire to save this 3%, but this item alone at the end of the year would be considerable. There are many other items which need not be mentioned. Perhaps this subject of the millman's comfort may be quite new to many mine managers, but I can assure them from personal experience it is an important one and too often sadly neglected.

A cyanide plant is a useful adjunct to a mill in cases, but a simple change in the details of the battery amalgamation may obviate its necessity. Find out where the values are escaping, whether in the fine or coarse material, and change the screen or take care of the gold-bearing tailings accordingly. Sometimes a change of screen to a coarser mesh will not only increase the tonnage, but lessen the values escaping; sometimes it is best to change to a finer mesh screen and crush less, but save more. Experiment and find out. Do not be content to have a mill and see it running, but have the mill save the great

est amount of gold at the least cost and then enjoy seeing it running.

Particularly a fast crushing mill should not be installed until it is determined whether the gold can be saved as fast as the ore is crushed, for a change to the ordinary old reliable five-stamp mortars may be a necessary step to saving values which otherwise escape.

### Precipitation of Gold and Silver From Cyanide Solutions.\*

NUMBER III—CONCLUDED.

Written by W. J. SHARWOOD.

It has been shown by others dealing with zinc shavings that the zinc does not accumulate in the solutions to any great extent, and that after a month or two the solutions do not change much in composition, even when used for several years. This is also true with zinc dust, as is shown by the following analyses, representing an experience of six months. It will be noticed, however, that the percentage of zinc in solution increased when the percentage of cyanide in the working solution was raised:

#### VARIATION IN COMPOSITION OF A CYANIDE SOLUTION WHEN PRECIPITATED BY ZINC DUST.

Number of days in use.....	0	10	40	70	100	130	160	190
Working strength KCN, % ..	.15	.10	.09	.09	.10	.10	.12	.12
Zinc, % .....	.034	.028	.025	.028	.032	.054	.050

Lime, % .....	.081	.091	.089	.100	.096	.082	.088	
Solid residue, % .....	.50	.56	.57	.67	.68	.60	.66	

Two men in one shift can easily clean up a press containing a ton of precipitate, and recloth it for use again. The cloths can be used for months, if they are protected by being covered with a light, cheap fabric, which can be stripped off and burned at the cleanup.

The following table shows the results obtained at some typical plants using zinc shavings and dust. The figures all represent experiences with thousands of tons of material. As a pound of zinc under ideal conditions should precipitate either 6 pounds (87 troy ounces) of gold, 3.3 pounds (48 troy ounces) of silver, or 1.95 pound (28 troy ounces) of copper, it is evident that the actual efficiency obtained in these instances is a very small fraction of the theoretical efficiency. This theoretical efficiency can only be approached when a rich solution is treated with a very small amount of zinc. On the other hand, it can be seen from the figures under "Percentage of Zinc Dissolved" that a large proportion, ranging from 16% to 60%, of the zinc remained undissolved in the precipitating boxes or presses. The percentage remaining undissolved is smaller when the solutions are strong and highly alkaline, when the proportion of solution to zinc is large, and when the period between cleanups is long. Two of these examples are from published statements; for some of the others I am indebted to several metallurgists who have kindly furnished me with valuable data.

#### RESULTS OBTAINED WITH ZINC PRECIPITATION IN UNITED STATES AND MEXICAN PRACTICE.

Material Treated at Plant.	Form of Zinc Used.	Percentage of KCN.	Average strength of solution when precipitated. Percent KCN.	Number of tons solution precipitated by one pound of zinc.	Percentage of zinc dissolved.	Number of Troy ounces precipitated by one pound of zinc.	Gold.	Silver.	Copper.
Sands, gold and silver.	Shavings	0.32	1.5	84	0.31	0.56	.....	.....	.....
Slime, gold and silver.	Shavings	0.04	5.	37	0.25	0.5	.....	.....	.....
Rich gold ore.	Shavings	0.5	1.1	40	1.100	0.10	.....	.....	.....
Mixed tailings, gold.	Shavings	0.1	3.3	60	0.700	0.01	Trace	.....	.....
Sand, gold and silver.	Shavings	0.2	3.2	79	0.16	3.19	None	.....	.....
Mixed tailings, gold and silver.	Dust.	0.1	2.	30	0.35	0.70	None	.....	.....
Low-grade sand, gold.	Dust	0.06	5.	84	0.700	0.30	.....	.....	.....
Mixed tailings, gold and silver.	Dust.	0.08	3.5	60	0.31	2.08	0.75	.....	.....
Low-grade slime, gold and silver.	Dust.	0.033	5.	66	0.12	0.83	1.20	.....	.....

In the last instance it was found possible to precipitate over 95% of the values from solutions which carried less than 50 cents gold and 10 cents silver per ton, with about 0.03% of free potassium cyanide. It is probable that the presence of copper had a favoring influence, but the result shows the zinc dust process to be as well adapted as the electrolytic to the precipitation of low-grade slimes solutions.

Some experiments were made on a solution carrying about \$2.50 in gold and 20 cents silver value per ton, together with 0.015% copper and 0.05% of free cyanide. One portion was treated with hydrogen sulphide until saturated; another was made distinctly acid and then allowed to stand until the precipitate of silver and copper cyanide settled, when it was filtered. Other portions were electrolyzed. It was found that precipitation was far from complete unless the current was allowed to act for a very long time, and the surface of the lead plates used was very large in proportion to the volume of solution. When this was done all traces of the gold and silver and copper were removed. Other portions were agitated with zinc dust at the rate of one-fourth pound per ton, without filter pressing, and others filter pressed.

Automatic Dumping Skips at the Pewabic Mine, Central City, Colo. (See Page 294)

#### EXPERIMENTS ON PRECIPITATION.

Method of Precipitation.	Percentage of Contents Precipitated.		
	Gold	Silver	Copper
Saturation with hydrogen sulphide.....	28	97	3
Acidulation .....	65	90	75
Electrolysis for 24 hours .....	100	100	100
Agitation 15 minutes with zinc dust ..	25	60	3
Agitation with zinc dust and filter pressing.	94	97	4

#### SIX MONTHS' EXPERIENCE WITH SIMILAR SOLUTIONS, USING ZINC DUST AND FILTER PRESSING.

KCN averaging 0.04% .....	98 to 99	Over 96	2 to 4
KCN from 0.08% to 0.1% .....	98 to 99	Over 96	0.5 to 1

These figures bring out the fact that silver is, as a rule, easier to precipitate than gold, just as it is slower to dissolve in cyanide solutions. Another instance of this was seen at a plant where it was at one time the practice to allow the values in the "strong solution" to accumulate for a week or more (there being more silver than gold), while the "weak solution" was always precipitated. The solution was sometimes made up to the required strength by putting a certain weight of the cyanide in lump form on the surface of the sand in the leaching vats, and then running on a measured amount of solution. This is not a very satisfactory method, but answered fairly well except when cyanide from a certain consignment was used, when a black deposit was always observed on the surface of the sand. This deposit for the most part redissolved in the course of a few hours. On examination it proved to be nearly pure silver sulphide, carrying a little gold and copper, while this particular brand of cyanide was found to contain an unusual proportion of alkaline sulphide. The trouble was prevented by using a purer brand of cyanide, or by precipitating the solution more frequently.

It is impossible to draw any general comparison between the merits of the different zinc and electrolytic methods of precipitation, but the following figures are based on practical results with material of moderately low value, all being calculated to a standard of 100 tons solution precipitated per day.

Electrolysis: Precipitating tank of 1200 cubic feet capacity for 100 tons solution daily—say, a box 10x5x24 feet—having about 3000 square feet each of anode and cathode surface. This would require 5 H. P. or 6 H. P. to produce current, in addition to the power for pumping. The actual precipitation obtained at two plants averages very close to 90% of the values in solution.

Zinc shavings: One hundred tons solution per day require about 100 cubic feet of capacity for the zinc, or about 175 gross cubic feet of zinc boxes—say, two boxes 2 feet by 2 feet 9 inches by 16 feet, using twenty-five to thirty pounds of zinc per day, the only power required being for pumping solution and turning zinc.

The actual precipitation obtained may be taken at 90% to 95% under favorable circumstances.

Zinc dust: One filter press, with sixteen frames about 2 feet square, would precipitate 100 tons, working not over fifteen or sixteen hours per day, and would require about 2 H. P. during that time—neglecting any additional friction in pumps in excess of the power required for pumping solution from sumps in the last case. Some power is also needed for stirring or agitating solution when adding zinc, but this is only for a few minutes at a time. The percentage of precious metals precipitated at two plants ranges from 95% to over 98%, from twenty to thirty pounds zinc dust being used per 100 tons.

Owing to the greater cost of the machinery required for the electrolytic and zinc dust processes, it is evident that the zinc shavings system is by far the best adapted to all small or temporary plants; but with installations intended to treat 100 tons or more per day, or likely to be in use for several years, the merits of the other systems should be considered.

SOME MODIFICATIONS OF THE CYANIDE PROCESS.—These notes are added in answer to a number of questions which have been asked of the writer since the title of this paper was announced.

The Pelatan-Clerici process was intended to render unnecessary the separation of the solution from the ore or tailings; these were to be agitated with the cyanide solution, while the precious metals were to be precipitated by electricity at the same time that dissolving was taking place; the gold was deposited on amalgamated copper plates attached to the bottom or sides of the tank, or suspended in it; common salt was added to the solution to increase the conductivity. It was tried at several mines in the United States, but for some reason or other was discontinued at each of them, and is only mentioned here on account of the resemblance which some more recent processes bear to it. The Riecken process, introduced into Australia, has a horizontal agitating shaft, the gold being similarly deposited by electrolysis during the agitation of the pulp, while a stream of quick-silver is kept flowing over the cathode plant. The Hendryx process also closely resembles the Pelatan-Clerici.

Two processes in use on rich ores in Western Australia are of interest, as both involve the use of the filter press to separate the solution, and also the practice of fine grinding in flint mills, which was discussed by Prof. S. B. Christy at the 1903 meeting of this Association, and which is coming into favor for certain classes of material. The Marriner process consists in first roasting the ore, fine grinding, agitating with cyanide solution, filter-pressing the pulp and precipitating the solution with zinc. The Diehl process consists in first grinding the ore fine, then agitating with bromo-cyanide, filter-pressing the pulp and precipitating. The working costs of each appear to be about \$5 per ton, the expense of bromo-cyanide in the one case being offset by that of roasting in the other.

## New System of Haulage Adapted to Heavy Grades.

Written for the MINING AND SCIENTIFIC PRESS by  
BENEDICT SHUBART.

Since the first installation of electric haulage it is fair to say that little has been done toward improving the old method of getting tractive effort from the friction due to the weight of a heavy locomotive on a smooth track. This has limited the field of the electric locomotive in mine work particularly, where grades are often beyond the safe limit of traction. In many mines there are still complex systems of ropes and drum hoists, making it necessary to couple and uncouple the trip several times before it reaches the open, and proving a constant source of expense and delay.

E. C. Morgan, who has been a pioneer in the design of electrical machinery for mining work, realized some years ago that there was a field as yet unoccupied, and bent his energy upon the perfection of a system of locomotive haulage that would do what a rope could do. The result has been the Morgan system of third-rail haulage. The Goodman Manufacturing Co. of Chicago has taken over Mr. Morgan's interests and are adding their experience to his. This change will doubtless result in a stronger and better machine than the original.

The present form of the third rail is the result of the best efforts of both companies.

Roughly speaking, the third rail system consists of a perforated rack fastened parallel to the rails, a sprocket wheel meshing in the rack, and the necessary motors for driving the sprocket wheel.

Cut No. 1 shows a sectional view of the third rail and track. Wooden stringers H, impregnated with a waterproof insulating solution, are laid upon the ties 5 inches off center to allow the miners room to walk along the track. Upon these are laid cross blocks of correct thickness to give the proper height to the impregnated strips on which is laid the third rail G. This is a strip of Swede's iron, approxi-

the sprocket wheel. This makes it impossible to come in contact with the charged third rail, except with deliberate intent. There is no record of an accident from contact with the charged rail.

The sprocket wheel is also insulated from the frame and wheels of the locomotive. Current is taken from the sprocket wheels by two brushes and the T rails

Fig. 4.—The Third-Rail Track.

Fig. 1.—Sectional View of Third Rail and Track.

Fig. 2.—The Morgan Locomotive.

mately  $4\frac{1}{2} \times \frac{3}{4}$  inches, cross section with accurately spaced square perforations, into which mesh the sprockets D. As in many installations the third rail carries the current to save the expense of trolley wire, it is necessary to make the third rail as safe as the ordinary track. To this end impregnated strips, not shown in the cut, are laid lengthwise along the third rail, leaving only a narrow slot for

are used for the return circuit as with the trolley locomotives.

The advantages claimed for the Morgan third-rail system are many. But first and foremost is the claim that almost any reasonable grade can be safely overcome in ordinary mining work. Grades as high as 20% are being operated at present, though this is a harder grade than should be attempted.

The Morgan third-rail is a positive haul. The difference between a Morgan locomotive and a traction locomotive is exactly the difference between a pair of spur gears and a pair of friction gears. One is positive and can be depended upon to drive; the other may slip at a critical point and do considerable damage. When the current is turned on in a Morgan locomotive it must start. Wet or greasy rails cannot hold it. Heavy grades cannot make it slip. And when the powerful screw brake is set it must stop. There is no skidding of a trip down a heavy grade beyond the control of the motorman.

Naturally there is no need of sand with this system. In the course of a year the expense of sand is an item to be considered, together with the annoyance of sanding machinery and extra wear on track and wheels.

A 25-ton traction locomotive has that excessive weight merely to gain friction on the track. A type "BB" Morgan locomotive weighs only  $4\frac{1}{2}$  tons, and yet has the same hauling capacity as the large traction machine. This means a saving of 20 tons of dead metal which need not be hauled about with every move of the locomotive. Conversely it means a gain of 20 tons of load in hauling capacity over a traction locomotive, with no greater expenditure of power. Or, a Morgan type "BB" locomotive will haul a 20-ton load with the same current that a traction locomotive uses in moving itself about.

Fig. 2 shows a Morgan third-rail locomotive of the latest type recently put into operation at the mines of the Barnard & Saginaw Coal Co. at Saginaw, Mich. This is an 80 H. P. motor, with a drawbar pull of 6000 pounds. The locomotive is built to run as a third-rail motor on the heavy grades and as a traction motor on the levels. Its weight is unusually heavy to secure tractive effort where the third rail is not laid.

At the mines of the Collins Colliery Co. at Glen Jean, West Va., the heavy grades necessitated the design of special locomotives. The equipment consists of two standard "BB" motors, and one each type 2B and type 4B motors. Fig. 3 shows the two special locomotives. It is evident that the 2B motor is made of two type "B" motors coupled together, and operated from one controller. Similarly the 4B locomotive is made of four type "B" motors. The motorman's station is midway of the length in each case, his seat, the controller and motor driven air brake pump being mounted there upon a suitable platform carried by the frames of the adjacent sections of the locomotive.

The starting drawbar pull of the two locomotives are 12,000 pounds and 24,000 pounds respectively.

Fig. 3.—Special Locomotives.

The weight of a traction locomotive equal to the larger machine would be 60 tons, whereas the weight of the Morgan locomotive is only 16 tons, and the weight on each wheel is but slightly more than the weight per wheel on the mine cars. Thus the Collins Colliery Co. were able to use their old track, whereas the adoption of traction motors would have meant relaying the entire trackage. Fig. 4 shows a por-

tion of the track where the 4B locomotive is hauling a load of 55 tons up a grade of 8%. The rear of the trip is in view at the head of the grade and the horse standing upon the track shows the safety of the insulation of the third-rail system. The trip was stopped half way around the curve so a photograph could be taken. Then the trip started on its upward path without hesitation, or even backing, to get the slack of the trip.

The remarkable success of the third-rail system induced the Goodman Manufacturing Co. first to exploit the sales and then to acquire the entire rights and manufacture of the machinery.

The Auditing of Ore Reserves.

In discussion of a paper read by B. I. Collings before the Chemical, Metallurgical and Mining Society of South Africa, H. L. Leopold said, at a recent meeting of that society, that he did not believe the "auditing" of mine sampling by another person would have the expected results ascribed by Mr. Collings to that idea. The following is abstracted from the remarks of Mr. Leopold:

In auditing ore reserves, several factors have to be considered, each of which requires careful investigation. But although a correct valuation of a mining property could not be made neglecting a single one of these, yet there is one of them which gives a great deal more trouble to the mining engineer than all the rest combined. I mean sampling. Proper sampling is an art, like any other, and a man who goes to his work with the idea that there is nothing easier than sampling had better not start at all. My opinion is that a sampler ought to be a man with a certain amount of technical education, be this education acquired at a school of mines or through years' experience in mines. He should have a keen, observing eye, a great deal of good sense, and take a lively interest in the work he does. A man with knowledge of geology, mineralogy, surveying and assaying should be given a preference, even if he has no underground experience. I think that these subjects and sampling are very intimately connected. To show that others think the same, I may quote the words of a well-known mine manager of the Eastern Rand, who said that a man cannot properly survey a reef unless he can sample it correctly. That gentleman was quite right. Only a sampler who has the above-named knowledge can be of effective assistance to the mine captain or surveyor.

We all know by experience that a reef has never exactly the same value over a great area and seldom the same width. We further know that some reefs carry the gold regularly and finely divided, but we also know that very often the reef is patchy. Other reefs carry the gold in coarse grains pretty equally distributed; some others, again, have the coarse gold in patches or zones. In the first and third instances there are not many chances for discrepancies if two independently taken samples are compared. But in cases two and four the results would almost always differ, and sometimes very considerably so.

Further, in development work (drives, winzes, etc.) samples are usually taken in the face and the assays entered on plan, and averages based on these figures. Check samples, on the contrary, would have to be taken by the auditor from the right or left wall, or from both, and we all know how much these differ. It would then remain to be decided whether the series of figures found by the auditor or that of the sampler, who knows the structure of the reefs by daily experience, is the more correct one. If I were asked what I thought would be the best method to check a sampler's work, I should say: Accompany him on his round and see that he takes his samples and measurements correctly from hanging to foot-wall, observing not only the dip—as many samplers think sufficient—but also the strike. Every other method of checking, especially in stopes, is ineffective.

I am very much tempted to draw a comparison between sampling and hoisting. Managers feel uneasy about the correct sampling of their properties, and look for a safety catch, but it has to be proved if the catch will act as and when required. Now the best safety in hoisting lies in a good rope, and to avoid serious discrepancies in the estimating of ore reserves, and the valuing of mining properties generally, a painstaking and reliable sampler affords the best security. Some mine managements have adopted the scheme of starting educated and energetic young men as samplers, and I daresay that this method promises to be the method of the future, as it has up to the present proved to be a complete success. For the young man who wishes to go ahead there need be no fear of an auditor coming to check his samples, as there is always the spur of ambition which keeps such a sampler from neglecting the precautions required to turn out a good day's work.

In sampling, just as in any other profession, it is not the quantity which gives credit, but the quality. I know by experience that from twenty to thirty samples is a very good day's work if they are taken accurately. Naturally, the number varies according to the locality and the nature of the rock. But the sampler's work is not done when he has taken the

Fairbanks, Alaska, Metropolis of the Tanana. (See Page 307.)

samples underground. Almost the same amount of trouble awaits him in the crushing house, where he has always to keep an eye on his samples and to take great care to carefully blow out the grinders after every sample. The most important job after the taking of the sample underground is undoubtedly the mixing, and many discrepancies in the estimating of ore reserves are due to the bad mixing of the samples which are sent in for assay.

Some time ago C. W. Lee, chief assayer at the Jumpers Deep, pointed out that samples, if not ground fine enough, would allow the gold to concentrate on the mixing cloth and, therefore, give inaccurate assay results. This is an undoubted fact, but I have found that even finely ground samples show a concentration towards the bottom if allowed to stand after the mixing. This concentration is most likely due to the fact that a sampling house is generally vibrating slightly, owing to machinery in motion near by. This vibration is, of course, transmitted to the shelves where the bags with the samples are.

Some samplers certainly would protest most emphatically if they were called inaccurate simply for pouring part of a ground sample from the big bag into a smaller one which is sent in for assay. Others are more accurate and mix their samples by rolling them on the cloth and afterwards spread them more or less evenly and take from different parts of the flattened heap the amount required for assay. This method, although the better of the two mentioned, is far from being accurate. The method called "quartering" is well known to all of us, so that I need not explain it further. At any rate, I find that quartering is best for, especially, important samples; it takes too much time for ordinary work.

I have, therefore, devised another method to quickly obtain a thorough, even sample. Rolling alone will not be sufficient, because of the gold concentrating on the cloth, though I do not condemn the use of the cloth, but its abuse. To mix properly, proceed as follows, using a scoop and cloth combined. Pour samples onto cloth, cross cut with the scoop through the heap in several directions, always throwing the lot on the scoop to the right and left alternately; roll a few times and repeat the above proceeding—the oftener the better. Flatten the heap into a fairly even layer about 1/2 inch thick, divide by cross lines, and take alternate squares, as on a chess board. If necessary, repeat to reduce to a convenient size. This quantity you treat as you did the whole before, and take from the equally spread layer what you want to send in for assay, always having the precaution to take equal parts from top and bottom of this layer. What remains on the cloth will be the best check sample.

I have put together some results taken from actual practice, which will clearly show a good sample can be totally spoiled by bad mixing. Of every sample three lots were assayed, fractions of pennyweights not being given:

MIXING WITH CLOTH ALONE (ROLLING).

PENNYWEIGHTS												
	1	2	3	4	5	6	7	8	9	10	11	12
1.....	117	44	13	6	8	19	12	26	58	15	16	6
2.....	130	42	15	9	10	18	9	23	54	11	10	2
3.....	112	46	16	9	11	11	16	22	59	12	21	8

MIXING WITH SCOOP AND CLOTH.

PENNYWEIGHTS												
	13	14	15	16	17	18	19	20	21	22	23	24
1.....	12	5	15	15	9	10	21	20	26	7	11	56
2.....	11	5	16	15	9	11	21	20	26	7	11	56
3.....	12	5	16	15	9	11	21	19	25	7	10	53

As will be seen, the results obtained by the first method are quite unreliable, while those taken by my method are strikingly uniform.

To prove that there is no concentration of gold on the cloth, if the sample be mixed properly, I have made the following experiments. I took from the mixed sample the whole of the top layer in three portions, without, as usual, including the bottom layer. These I sent in for assay, as well as the part remain-

ing immediately on the cloth. The results proved very satisfactory indeed. They are as follows:

PENNYWEIGHTS					
	1	2	3	4	5
1—Top layer.....	5	11	12	17	5
2—Top layer.....	5	11	11	17	5
3—Top layer.....	5	10	12	17	5
Bottom layer.....	3	11	12	17	5

You will notice that the slight variations in the results from my method of mixing cannot be due to concentration, as they are all below the average. These, the assayer assures me, are due to loss through absorption during cupellation, the buttons not being parted. It is hardly necessary to point out how impossible it is for the monthly returns to correspond to the calculated figures when assays may differ by four pennyweights or more, owing to faulty mixing.

To conclude, I would like to suggest that the schools of mines in England, America and on the Continent should pay much more attention to sampling than they do at the present time. A young mining engineer may spoil his career through lack of knowledge in sampling, and, therefore, I hope that soon all schools of mines may give it the importance it deserves.

THE PROSPECTOR.

The rocks from North Yamhill, Or., have been identified as follows: No. 1 is graywacke (a peculiar sandstone). No. 2 is an altered and silicified dike rock in which is much disseminated pyrite. No. 3, obsidian (volcanic glass). No. 4 is apparently a piece of petrified wood, which was originally a portion of a tree buried in the lava. No. 5 consists chiefly of small fragments of feldspar and quartz cemented by indurated clay. No. 6, volcanic glass, containing many spherules, and is undergoing devitrification. Any metal obtained by heating in the forge, as claimed, is probably iron. No. 7, volcanic tuff. No. 8 and No. 9, vitrophyre (volcanic glass). No. 10 is much altered granular rock, in which quartz grains and kaolinized feldspar are noticeable. The green mineral is iron silicate. The rock is so much altered as to make its original character indeterminable. No. 11, volcanic tuff, with fragments of basic lava. No. 12, quartz, carrying considerable galena, a little zinc sulphide (blende), and stains of iron and copper. This should contain also silver and gold. No. 13, quartz and talc, stained by green copper carbonate; may also contain gold. It is practically talc schist, with veinlets of quartz. No. 14, bluish quartz, with abundance of pyrite and marcasite, both iron sulphides. Rock of this description is often very rich in gold, but not always free milling. No. 15, chalcedonic quartz, stained red by iron oxide—hematite. Rocks of this character are occasionally gold bearing. No. 16 is largely composed of chlorite, and is undoubtedly an altered greenstone. There is considerable iron oxide present. It is not necessarily a vein mineral, but may occur in a zone of mineralization. No. 17, iron-stained clay, seemingly a very much altered greenstone, such as diabase or diorite. Such rocks are often gold bearing at and near the surface, but in depth the values are likely to become low grade or disappear entirely from the country rock, though seams of quartz or lime (calcite) occurring in them may be found rich in gold in depth.

The rocks from Good Springs, Nev., are: No 1 (black), brecciated limestone recemented by calcium carbonate and containing considerable iron; No. 2, iron-stained quartz with granular structure, probably replacement of limestone. This may contain gold or silver; No. 3 (white), calcite, crystallized limestone.

## Oil and Asphaltum on the Shores of Great Salt Lake, Utah.

Written for the MINING AND SCIENTIFIC PRESS by  
DON MAGUIRE.

Wyoming and Colorado promise to make great additions to the field of America's oil region. For more than twenty years—that part of Colorado around Florence has been a profitable field of production and other parts of that State promise to become more prolific than the Florence district. In Wyoming oil and asphaltum should be abundant. As far back as 1812, "tar springs" were known in Wyoming. From present indications, based on the work of prospecting, Wyoming is destined to become one of the great oil fields of the world; western Wyoming especially shows evidence of its existence.

of faulting in our country. Originally the valley of Great Salt Lake was a deep basin. At present its surface is 4200 feet above sea level where formerly it was only about 2000 feet above sea level. In other words, we find now 2200 feet of sediment lying between the bottom of the waters of the lake and the point where the oil drill shows rock in place. This depth refers to that part of Salt Lake basin lying between the east shores of the lake and New Foundland butte, that rises out of the desert 15 miles west of the lake shore. Underneath this vast depth of soft sediment, carried from the regions surrounding the great basin during recent geological time, lie the rocks that in other localities form the casing for extensive oil deposits.

For upwards of thirty years natural gas has been known to exist in this area and at Salt Lake City this was utilized for about five years, but in a limited way, as the pressure does not seem to have been sufficiently continuous to make its use satisfactory—

Bonneville shore line, is found a clay that on being exposed to great heat will give an odor similar to heated asphaltum. This barren condition does not, however, exist all over the Salt Lake basin, for in the northwest region of the lake—taking that part of the water area that lies west of the Promontory mountains where the waters of the lake of late years have receded far within their former meander line—we find an oil and asphaltum field covering an area of about 150 miles.

For ten years reports were heard that asphaltum had been discovered south of Promontory on the lake shore, but no persons of prominence in the mining world gave credence to them. About thirty years ago I visited that margin of the lake, but, as in those days, the waters of the lake reached much farther to the north than they do at the present day. They washed a shore where there is nothing but basalt, and, knowing this, when reports of oil and asphaltum discoveries were made, they were not believed. Persistent statements continued to be made and the writer in November, 1903, in company with others, visited the reported site of these discoveries to find that the lake had receded far beyond the old meander line, exposing a wide stretch of country free from lava, and that along the lake shore and far out into the lake, a number of small islets served as vents for asphaltum exudations. There are about 100 of these scattered up and down the lake shore for a distance of 10 miles and extending into the shallow waters of the lake; they either show their crests above the surface or appear plainly, rising from the lake bottom below, as in all places where either oil or asphaltum is found by a lake or sea shore we find rolls and masses of sand asphaltum along this part of the shore of Great Salt Lake. The quantity of asphaltum existing at any of these vents is not large. Where a limited amount of work had been done some years ago, and a cylinder formed from a section of a steam boiler had been driven down, we found a volume of viscous asphaltum equivalent to about ten barrels. At each of the other islets or vents from a few gallons to perhaps a barrel might be gathered up. The character of this asphaltum is much the same as that found along the California coast from Santa Barbara to San Pedro, where oil exists abundantly. As to its existence in large quantity here, we know, as yet, next to nothing—that is, the public know nothing. Some time after the visit to the above district two companies were formed—one the Great Salt Lake & Promontory Oil & Asphaltum Co., the other the Utah Asphaltum & Oil Co. One has sunk a well 1400 feet, the results of which are known only to themselves. They have, however, been securing additional areas beyond those first held by them.

The oil vents on the flats extend far to the south, and from each vent flows water less saline than the brine of the lake. With this water slowly oozes the liquid asphaltum. At no time in the past does there seem to have been a greater flow of asphaltum than now. When the water rose high above its present level there was no evidence of its existence there; and far out into the lake, where the water reaches a depth of 12 to 20 feet, the evidence of the asphaltum being in greater quantity may exist, but at that depth no one has yet made any investigation. Even along the shore the student or prospector who visits the spot, unless he can ferret information from the management of the 1400-foot bore hole, can only know that at one point on the north shore of Great Salt Lake oil and asphaltum exist in at least limited quantity and exposed on the surface over considerable area. The rock formation in the Promontory to the eastward is almost entirely of Cambrian—slates and Silurian limestones containing few fossils. Save where the green sandstone outcrops at a few points along the lake, the lake sediments cover the flat surface of the desert. Fifty miles to the southwest the Southern Pacific Railway Co. have gone down 2700 feet for fresh water, and salt water carrying much sulphuric acid has been encountered.

The gold output of the Rand in South Africa is gradually increasing from month to month, the output for the month of March being officially stated to have been 385,575 ounces. This is at the rate of over \$90,000,000 per annum—a greater output than has ever been reached on that field. With the more extensive opening of the deep levels this output will continue to increase, and will, without doubt, unless something at present unforeseen occurs, pass the hundred million dollar mark. The output of over \$7,700,000 per month for a mining section not over 40 miles in length, and a great portion of that unproductive and undeveloped, is an interesting thing to contemplate from almost any standpoint.

A COMPARISON of working costs in mine operation is only of value when all the conditions at the several mines, of which a comparison is made, are known. These conditions comprise a variety of things, among them the size of the vein or ore deposit; hardness of the rock; method of mining, timbering and filling; cost and efficiency of labor; transportation cost; situation and depth of the mine; amount of water to be handled, and a great many minor things, but all of which add materially to the aggregate cost.

Where the Oil Seeps From the Ground, Great Salt Lake, Utah.

At the Oil Well, Great Salt Lake, Utah.

In 1878 oil wells were in operation in eastern Wyoming, near Jenny's Stockade, the oil being used by the Black Hills mines. Utah is the youngest region wherein capital has given attention to searching for either asphaltum or oil. For about fifteen years the mining of the hydrocarbons has been profitably carried forward, in Carbon, Uinta and Utah counties, gilsonite, elaterite, ozokerite and crude asphaltum being mined at many points within this area—gilsonite particularly, which is a hard, dry and almost chemically pure asphaltum, being abundant in fissures in the red sandstone, near Fort Duchesne, in Uinta county. The chief feature of this sketch, however, is the subject of gas, oil and asphaltum in the Great Salt Lake valley. This valley proper, measuring it from the town of Malad in southern Idaho to the point of the mountains, 20 miles south of Salt Lake City, is about 112 miles from north to south, and in width from east to west about 100 miles. On its western borders several important mountain spurs rise from the broken plain and, on the eastern side of the valley, the rugged, bold and far-extending Wasatch range presents one of the most conspicuous examples

and to-day it has fallen into disuse.

Turning to the more important subject of oil and asphaltum, the existence of either was not thought probable within the above area until recently. Those who carried out the work of the United States Geological Survey within the valley during the '70s and '80s do not touch upon the subject, and it was not until about the year of 1890 that any one thought of investigating.

From the year 1890 to 1900 attempts were made on the east shore of the lake, between Salt Lake City and Farmington, to discover oil, the borings being shallow, and no discoveries were made. Over this same area during the past five years parties from Pittsburg, Pa., have gone to a considerable depth to ascertain if oil exists in that part of the valley. As to the results of these investigations, no one, save the employees, know anything, and such knowledge as they possess will probably be kept secret.

As to the surface indications for oil or asphaltum on the east shores of the Great Salt Lake, none are known unless where, in the clay banks near the

## The Law in Tunnel Site Cases.

In the past it has been the policy of this paper to publish in full the text of important decisions of the United States Supreme Court. The opinion of the highest Federal Court becomes law and is of greater importance and effect than the statutes themselves, for the statutes are never considered good law until the Supreme Court has been called upon to interpret their meaning. The recent opinion of this court in the case of the Creede & Cripple Creek M. & M. Co., petitioner, vs. the Uinta Tunnel M. & T. Co., which opinion was written by Justice Brewer, is one of the most important decisions handed down by the Supreme Court in recent years and places a new construction on an important phase of the mining law. The opinion in full is as follows:

The Creede and Cripple Creek Mining and Milling Company, Petitioner, vs. The Uinta Tunnel Mining and Transportation Company.

On writ of certiorari to the United States Circuit Court of Appeals for the Eighth Circuit.

[January 30, 1905.]

Mr. Justice Brewer delivered the opinion of the Court.

Certiorari to review a judgment of the United States Circuit Court of Appeals for the Eighth Circuit, (119 Fed. Rep. 164), reversing a judgment of the Circuit Court of the United States rendered upon a verdict of a jury directed by the court.

The action was originally brought by the Creede and Cripple Creek Mining and Milling Company as plaintiff against The Uinta Tunnel Mining and Transportation Company as defendant, in the District Court of the county of El Paso, Colorado, for the possession of certain mining claims and for damages. Equitable relief was also prayed. On motion of the defendant the action was removed to the United States Circuit Court for the District of Colorado, where, also on its motion, the pleadings were reformed and the action made one for the possession of the property and damages.

The plaintiff filed an amended complaint, alleging in substance that it was the owner in fee and in possession and entitled to the possession of the Ocean Wave and Little Mary lode mining claims—being survey lot No. 8192, evidenced by mineral certificate No. 338, the patent of the United States to said plaintiff for said claims bearing date December 21, 1893—that said claims were duly located and discovered on the 2d of January, 1892, and that the patent related back and took effect of that date for all purposes given and provided by the laws of the United States and the State of Colorado concerning mining claims.

Entry upon the claims and ouster of plaintiff by defendant by means of its tunnel were also alleged.

Thereafter the defendant filed its answer. Upon motion of plaintiff certain portions thereof were stricken out, and on the trial testimony offered by the defendant in support of the portions stricken out was rejected.

The matter to be determined is the sufficiency of the defenses pleaded and stricken out. To appreciate them fully it is well to state some facts about which there is no dispute, and it is sufficient to state the facts in reference to one of the lode mining claims, as the proceedings in respect to the two were alike. On February 1, 1892, J. B. Winchell and E. W. McNeal filed in the office of the county clerk of El Paso county (the county in which the mining claim was situated) a certificate of location which, not verified by affidavit or other testimony, stated that they had on January 2, 1892, located and claimed, in compliance with the mining acts of Congress, 1500 linear feet on the Ocean Wave lode, and gave the boundaries of the claim. By several mesne conveyances the title of Winchell and McNeal passed to the plaintiff. On August 5, 1893, the plaintiff made an entry of the claim in the proper land office of the United States, and, no proceedings in adverse being instituted, a patent therefor was issued to it on December 21, 1893. There is no reference in the patent to the discovery or the filing of the location certificate. The first appearance of the claim on the records of any office of the United States is the entry in the local land office of August 5, 1893, and the only prior record in any State office is the location certificate, unsworn to, filed February 1, in which the parties filing the certificate stated that they had discovered the lode on January 2, 1892. On February 25, 1892, a location certificate of the defendant's tunnel was filed in the office of the county clerk of El Paso county, which, verified by the oath of one of the locators, stated that on January 13, 1892, they had located the tunnel site by posting in a conspicuous place and at the entrance to the tunnel a notice of their intent to claim and work the tunnel; that they had performed work therein to the value of \$270 in driving said tunnel and \$80 in furnishing and putting in timbers, and that it was their bona fide intent to prosecute the work with diligence and dispatch for the discovery of lodes and for mining purposes. The certificate also contained a full description of the boundaries of the tunnel site as claimed.

In a general way it may be said that the defenses which were stricken out were a priority of right and an estoppel. We quote these paragraphs from the answer:

"It further avers that the patent of the United States issued for said Ocean Wave and Little Mary lodes and lode mining claims was issued subject to the act of Congress in reference to tunnel rights and subject to the laws of the State of Colorado in reference to the right to run tunnels through ground that may be patented, for the purpose of reaching territory that belongs to tunnel owners beyond such patented claims, and subject to the rights which the defendant The Uinta Tunnel Mining and Transportation Company and its grantors had acquired by reason of the location of said Uinta tunnel,

and in and to any and all lodes, veins, and mining claims that it might cut or discover in driving said tunnel, as is guaranteed to the locator of said tunnel under and by virtue of Section 2323 of the Revised Statutes of the United States; that the pretended discovery alleged and pretended to have been made in and upon said pretended Ocean Wave and Little Mary lodes and lode mining claims, and by virtue of which the plaintiff claims the right to patent the same under the laws of the United States, was not made until long after the location of said Uinta tunnel, and at the time said pretended locations were made said locators thereof were advised and knew that said tunnel had been located and had been and was being prosecuted with due diligence and in strict compliance with the terms and conditions of the statutes of the United States and of the State of Colorado, which authorize and provide for the location and prosecution of such tunnels and which define and determine the rights pertaining thereto; and that said pretended Ocean Wave and Little Mary lode mining claims, so far as the same may be now claimed and possessed by said plaintiff, were taken and held subject to the rights of this defendant as owner of said Uinta tunnel, located in accordance with section 2323 of the Revised Statutes of the United States, and also subject to the rights of this defendant to cross said claims and to drive drifts therein and to follow said lode claims as located by this defendant and to reach lode claims so owned by this defendant, as hereinbefore and hereinafter stated.

"It alleges that it and its grantors have expended in and upon said tunnel the sum of more than one hundred and twenty-five thousand dollars (\$125,000), and in addition to said expenditures have also expended upon surface work, in improvements and expenses, the further sum of not less than ten thousand dollars (\$10,000).

"It alleges that its work and the work of its said grantors in and upon said tunnel has been done openly and without concealment; that the same has been at all times prosecuted under the claim of the defendant and its grantors of the right so to do by virtue of the location of said tunnel and tunnel site location, under and by virtue of the laws of the United States, and under the provisions of section 2323 of the Revised Statutes of the United States; and that the expenditures thereof and the developments made thereon have been made in compliance with the terms and provisions of and in reliance upon said statute.

"That the plaintiff, by permitting and allowing this defendant to expend more than the sum of one hundred and thirty-five thousand dollars (\$135,000) as aforesaid in reaching, uncovering and discovering said ore body, has no right to interfere with the defendant in operating its tunnel over, through and along said pretended Ocean Wave and Little Mary lodes and lode mining claims, but that, on the contrary, the plaintiff by its conduct and actions in the premises as hereinabove recited and set forth has permitted and allowed said defendant to expend said sum of one hundred and thirty-five thousand dollars (\$135,000), and has permitted and allowed the defendant so to proceed with said tunnel through and across said pretended Ocean Wave and Little Mary lodes and lode mining claims until the same has ripened into such a license and permission as entitles the defendant to use its said tunnel as it penetrates said pretended Ocean Wave and Little Mary lodes and lode mining claims, and that said license and permission is such that the defendant cannot be disturbed therein."

It was also alleged that the tunnel had been driven some 2200 feet; that it entered the ground of the plaintiff at about 550 feet from its portal, and in running through that ground the tunnel was driven 625 feet, leaving the plaintiff's ground at about 1175 feet from the portal; that after passing it the defendant discovered in the tunnel three or four blind lodes, which it duly located; and it was not until after the discovery and location of these lodes that the plaintiff commenced this action.

Was there error in striking out these defenses? By section 2319, R. S., "all valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase." Until, therefore, the title to the land passes from the Government the minerals therein are "free and open to exploration and purchase." A lode locator acquires a vested property right by virtue of his location, (*Clippier Mining Co. v. Eli Mining & Land Co.*, 194 U. S. 220,) but what is the extent of that property right? Section 2322 defines it as follows: "The locators \* \* \* shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of such surface locations." The express grant to the locator made by this section includes only the surface and the veins apexing within the boundaries of the location. Until, therefore, by entry and payment to the Government, the equitable title to the ground passes to the locator, he is in no position to question any rights of exploration which are granted by the other provisions of the statute. The fee still remains in the Government. By section 2320 it is provided that "no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located." And by section 2324: "The miners of each mining district may make regulations not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located, by reference to some natural object or permanent monument, as will identify the claim." Tunnel rights are granted by section 2323, which reads:

"Where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins

or lodes within three thousand feet from the face of such tunnel on the line thereof, not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface; and locations on the line of such tunnel of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, shall be invalid; but failure to prosecute the work on the tunnel for six months shall be considered as an abandonment of the right to all undiscovered veins on the line of such tunnel."

It does not appear from the answer or testimony that the tunnel had reached the boundaries of the plaintiff's claims prior to the entry or even prior to the patent. For the purpose of this case, therefore, we must assume that, although its line had been marked out—a line extending through the plaintiff's ground—yet in fact no work had been done within such ground prior to the patent.

The propositions upon which the plaintiff relies are that discovery is the initial fact; that the patent when issued relates back to that initial fact and confirms all rights as of that date; that no inquiry is permissible as to the time of that discovery, it being concluded by the issue of the patent; that such time antedated anything done in or for the tunnel; that no adverse proceedings were instituted after it had applied for patent, and that, therefore, its right became vested in the ground, the same right which any other land owner has, and which could not be disturbed by the defendant by means of its tunnel. (*St. Louis Mining Company v. Montana Mining Company*, 194 U. S. 235.)

On the other hand, defendant contends that, as the first record in any office of the Government was the record of the entry on August 5, 1893, the patent issued in an ex parte proceeding is conclusive only that every preceding step, including discovery, had then been taken; that it in fact located its tunnel site prior to any discovery or marking on the ground of plaintiff's claim; that it was not called upon to adverse plaintiff's application for a patent, because no patent is ever issued for a tunnel, and it had not then discovered any veins within its tunnel; that plaintiff, with full knowledge of defendant's tunnel location, permitted the driving of the tunnel through its ground and beyond, at an expenditure of \$135,000, and made no objection until the discovery of the veins beyond its ground, and then for the first time and to prevent defendant from developing such veins brought this action, and that by such acquiescence it was now estopped to question defendant's use of the tunnel.

Obviously the parties divide as to the effect of plaintiff's patent. The Circuit Court held with the plaintiff, the Court of Appeals with the defendant. It may be conceded that a patent is conclusive that the patentee has done all required by law as a condition of the issue; that it relates to the initiation of the patentee's right and cuts off all intervening claims. It may also be conceded that discovery of mineral is the initial fact. But when did the initial fact take place? Are all other parties concluded by the locator's unverified assertion of the date or the acceptance by the Government of his assertion as sufficient with other matters to justify the issue of a patent? Undoubtedly, so far as the question of time is essential to the right, the patent is conclusive, but is it beyond that?

In order to reach a clear understanding of the question it seems necessary to consider the legislation. Three things are provided for, discovery, location and patent. The first is the primary, the initial fact. The others are dependent upon it and are the machinery devised by Congress for securing to the discoverer of mineral the full benefit of his discovery. Chap. 6 of Title 32, R. S., is devoted to the subject of "Mineral Land and Mining Resources." The first section, 2318, reserves mineral lands for sale, except as expressly directed. The next provides that all valuable mineral deposits in Government lands shall be free and open to exploration and purchase and the lands in which they are found to occupation and purchase. In the next it is declared that no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim. The whole scope of the chapter is the acquisition of title from the United States to mines and mineral lands, the discovery of the mineral being, as stated, the initial fact. Without that no rights can be acquired. As said by Lindley, in his work on Mines, 2d ed., vol. 1, sec. 335:

"Discovery in all ages and all countries has been regarded as conferring rights or claims to reward. Gamboa, who represented the general thought of his age on this subject, was of the opinion that the discoverer of mines was even more worthy of reward than the inventor of a useful art. Hence, in the mining laws of all civilized countries the great considerations for granting mines to individuals is discovery. 'Rewards so bestowed,' says Gamboa, 'besides being a proper return for the labor and anxiety of the discoverers, have the further effect of stimulating others to search for veins and mines, on which the general prosperity of the State depends.'"

Location is the act or series of acts by which the right of exclusive possession of mineral veins and the surface of mineral lands is vested in the locator. For this the only requirement made by Congress is the marking on the surface of the boundaries of the claim. By section 2324, however, Congress recognized the validity of any regulations made by the miners of any mining district not in conflict with the laws of the United States or the laws of the State or Territory within which the district is situated. This is held to authorize legislation by the State. Thus in *Belk v. Meagher*, 104 U. S. 279, 284, it was said:

"A location is not made by taking possession alone, but by working on the ground, recording and doing whatever else is required for that purpose by the acts of Congress and the local laws and regulations."

In *Kendall v. San Juan Mining Company*, 144 U. S. 658, 664, is this language:

"Section 2324 of the Revised Statutes makes the manner of locating mining claims and recording them subject to the laws of the State or Territory, and the regulations of each mining district, when they are not in conflict with the laws of the United States."

See also *Erhardt v. Boaro*, 113 U. S. 527, 533, 534, 535; *The Butte City Water Company v. Baker*, 196 U. S.

And many Territories and States (Colorado among the number) have made provisions in respect to the location other than the mere marking on the ground of the boundaries of the claim. So before a location in those States is perfected all the provisions of the State statute as well as of the Federal must be complied with, for location there does not consist in a single act. In *Morrison's Mining Rights*, (11th ed.) p. 37, the author, having primarily reference to the laws of Colorado, says:

"The location of a lode consists in defining its position and boundaries, and in doing such acts as indicate and publish the intention to occupy and hold it under the license of the United States. The formal parts of location include: 1, the location notice at discovery; 2, the discovery shaft; 3, the boundary stakes."

In *Smelting Company v. Kemp*, 104 U. S. 636, 649, Justice Field, referring to the fact that the terms "location" and "mining claim" are often indiscriminately used to denote the same thing, says by way of definition: "A mining claim is a parcel of land containing precious metal in its soil or rock. A location is the act of appropriating such parcel, according to certain established rules."

See also *Northern Pacific R. R. Co. v. Sanders*, 49 Fed. Rep. 129, 135.

The patent is the instrument by which the fee simple title to the mining claim is granted.

Returning now to the matter of location, the Colorado statutes in substance require:

"1. To place at the point of discovery, on the surface, a notice containing the name of the lode, the name of the locator and the date of the discovery.

"2. Within sixty days from the discovery, to sink a discovery shaft ten feet deep showing a well-defined ore vein.

"3. To mark the surface boundaries by six posts, one at each corner and one at the center of each side line, hewed or marked on the side or sides in towards the claim.

"4. The disclosure of the lode in an open cut, cross cut or tunnel suffices instead of a ten-foot shaft.

"5. Within three months from date of discovery he must file a location certificate with county recorder giving a proper description of the claim, and containing also the name of the lode, the name of the locator, the date of the location, the number of feet in length on each side of the center of the discovery shaft and the general course of the lode." (*Morrison's Mining Rights*, 11th ed. p. 59.)

The issue of a patent for a lode claim in Colorado is therefore not only a conclusive adjudication of the fact of the discovery of the mineral vein, but also of compliance with these several provisions of its statutes. The Supreme Court of that State has decided that the order is not essential, providing no intervening rights have accrued. In *Brewster v. Shoemaker*, 28 Col. 176, 180, it said:

"The order of time in which these several acts are performed is not of the essence of the requirements, and it is immaterial that the discovery was made subsequent to the completion of the acts of location, provided only all the necessary acts are done before intervening rights of third parties accrue. All these other steps having been taken before a valid discovery, and a valid discovery then following, it would be a useless and idle ceremony, which the law does not require, for the locators again to locate their claim and refile their location certificate, or file a new one."

And that has been the general doctrine. In 1 *Lindley on Mines* (2d ed.) sec. 330, the author says:

"The order in which the several acts required by law are to be performed is non-essential, in the absence of intervening rights. The marking of the boundaries may precede the discovery, or the discovery may precede the marking; and if both are completed before the rights of others intervene, the earlier act will inure to the benefit of the locator. But if the boundaries are marked before discovery, the location will date from the time discovery is made."

In 1 *Snyder on Mines*, sec. 354, it is said:

"While the general rule is, as stated elsewhere in the foregoing sections, that a location must rest upon a valid discovery, yet a location otherwise good, with a discovery made after location and before the intervention of adverse claims or the creation of adverse rights, will validate the location from the date of discovery, and generally from the first act towards claim and appropriation—this by relation."

In *Morrison's Mining Rights* (11th ed.) p. 32:

"If a location be made before discovery, but is followed by a discovery in the discovery shaft, before any adverse rights intervene, such subsequent discovery cures the original defect and the claim is valid."

In *re James Mitchell*, 2 L. D. 752, it was held by Commissioner McFarland that, "although prior to location no discovery of mineral was made within the ground claimed, upon a subsequent discovery prior to application for patent the location became good and sufficient, in the absence of any adverse rights."

In *Reins v. Raunheim*, 28 L. D. 526, 529, Secretary Hitchcock declared that "it is immaterial whether the discovery occurred before or after the location, if it occurred before the rights of others intervened. *Erwin v. Perego et al.*, 93 Fed. Rep. 608."

Reference is made to the statement of Secretary Smith in *Etling v. Potter*, 17 L. D. 424, 426, as though that announced a different conclusion, that "a location certificate is but one step, the last one, in the location of a mining claim." But a location certificate is simply a certificate required by the local statute or custom that some things have been done, and, of course, it must come after those things have been done.

Again, in the same volume, pp. 545 and 546, *Northern Pacific Railroad Company v. Marshall*, he said:

"In the location of a mineral claim, placer or lode, the first requirement of the law is a discovery. (Secs. 2319 and 2320 Rev. Stat.) All rights inuring to the benefit of the locators are based upon this initial act. (*Erhardt v. Boaro*, 113 U. S. 537; *United States v. Iron Silver Mining Company*, 128 Id. 673; *O'Reilly v. Campbell*, 116 Id. 418.) When, therefore, a legal location has been made

on land returned as agricultural, the slight presumption in favor of the return of the surveyor general is, ipso facto, overcome, and the burden of proofs shifts to the party attacking such mineral entry. By such discovery and location it is demonstrated that the return was erroneous, and it would be trifling with physical facts to put the onus on the locator to present further evidence until it is shown that, as a matter of fact, he had no discovery."

But the question he was considering was simply as to the burden of proof between one claiming land returned as agricultural land and one claiming a portion thereof, as an apparently legal location of a mineral claim.

In *North Noonday Mining Company v. Orient Mining Company*, 1 Fed. Rep. 522, 531, Judge Sawyer, in charging the jury, said:

"I instruct you, further, that if a party should make a location in all other respects regular, and in accordance with the laws, and the rules, regulations and customs in force at the place at the time, upon a supposed vein, before discovering the true vein or lode, and should do sufficient work to hold the claim, and after such location should discover the vein or lode within the limits of the claim located, before any other party had acquired any rights therein, from the date of his discovery his claim would be good to the limits of his claim, and the location valid."

To the same effect was the charge of the same judge in *Jupiter Mining Company v. Bodie Mining Company*, 11 Fed. Rep. 666, 676.

In *Cedar Canyon Mining Company v. Yarwood*, 27 Wash. 271, the Supreme Court of Washington ruled that

"In the absence of intervening rights, the fact that mineral is not discovered on a claim until after the notice of location is posted and the boundary mark is immaterial, and, where the discovery is the result of work subsequently done by the locator, his possessory rights under his location are complete from the date of such discovery." (*Nevada Sierra Oil Co. v. Home Oil Co.* [C. C.] 98 Fed. Rep. 673; *Erwin v. Perego*, 35 C. C. A. 482, 93; Fed. Rep. 608; *Jupiter Min. Co. v. Bodie Consol. Min. Co.* [C. C.] 11 Fed. Rep. 666; 1 *Lindl. Mines*, s. 335, and cases cited.)

See especially *Erwin v. Perego*, cited in this quotation, decided by the Court of Appeals for the Eighth Circuit. Tending in the same direction are *Thompson v. Spray*, 72 Cal. 528, 533; *Gregory v. Pershbaker*, 73 Cal. 109, 118; *Tuolumne Consol. Min. Co. v. Maier*, 134 Cal. 583, 585.

But what is the meaning of the statute? Its language is "no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located." Does that require that a discovery must be made before any marking on the ground, especially when as under the Colorado statutes several other steps in the process of location are prescribed, or does it mean that no location shall be considered as complete until there has been a discovery? Bearing in mind that the principal thought of the chapter is exploration and appropriation of mineral, does it mean anything more than that the fact of discovery shall exist prior to the vesting of that right of exclusive possession which attends a valid location?

This may be looked at in another aspect. Suppose a discovery is not made before the marking on the ground and posting of notice, but is then made, and it and all other statutory provisions are complied with before the entry which is an application for the purchase of the ground, of what benefit would it be to the Government to require the discoverer to repeat the marking on the ground, the posting of notice, and other acts requisite to perfect a location? If everything has been done which under the law ought to be done to entitle the party to purchase the ground, wherein is the Government prejudiced if the precise order of those acts is not followed? Or, to go a step farther, suppose, on an application for a patent, an adverse suit is instituted, and on the trial it appeared that the plaintiff in that suit had made a discovery and taken all the steps necessary for a location in the statutory order, although not until after the applicant for the patent had done everything required by law, would there be any justice in sustaining the adverse suit and awarding the property to the plaintiff therein on the ground that the applicant had not made any discovery until the day after his marking on the ground, and so the discovery did not precede the location?

These suggestions add strength to the concurring opinion of three leading commentators on mining law, the general trend of the rulings of the department and decisions of the courts, to the effect that the order in which the several acts are done is not essential, except so far as one is dependent on another. Doubtless a locator does not acquire the right of exclusive possession unless he has made a valid location, and discovery is essential to its validity, but if all the acts prescribed by law are done, including a discovery, is it not sacrificing substance to form to hold that the order of those acts is essential to the creation of the right? It must be remembered that the discovery and the marking on the ground are not matters of record but in pais, and if disputed in an adverse suit or otherwise must be shown, as other like facts, by parol testimony. It must also be remembered that the certificate of location required by the Colorado statutes need not be verified. The one in this case was not. A locator might, if so disposed, place the date of discovery before it was in fact made, and at any time within three months prior to the filing of the certificate.

But it has been said that the question has been decided by this court adversely to these views, and *Enterprise Mining Company v. Rico-Aspen Mining Company*, 167 U. S. 108; and *Calhoun Mining Company v. Ajax Mining Company*, 182 U. S. 499, are cited. In the former case the question was as to when a vein discovered in a tunnel must be located, and in the opinion (page 112) we said:

"In order to make a location there must be a discovery; at least, that is the general rule laid down in the statute. Section 2320 provides: 'But no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located.' The discovery in the tunnel is like a discovery on the surface. Until one is made there is no right to locate a claim in

respect to the vein, and the time to determine where and how it shall be located arises only upon the discovery—whether such discovery he made on the surface or in the tunnel."

But that comes far short of meeting the question before us. It is undoubtedly true that discovery is the initial fact. The language of the statute makes that plain, and parties may not go on the public domain and acquire the right of possession by the mere performance of the acts prescribed for a location. But the question here is whether, if there be both a discovery and the performance of all the acts necessary to constitute a location, the order in which these things take place is essential to the right of exclusive possession which belongs to a valid location?

In the *Ajax* case the contest was between mining claims on the one hand and a mining claim and tunnel site on the other. All the mining claims had passed to patent. The plaintiff in error, who was defendant below, held the junior patent issued upon a later entry, and the entries of plaintiff's claims were made and the receiver's final receipts issued prior to the location of the tunnel site. In other words, the defendant, admitting that its right to a tunnel had not been established by a location at the time of the entries of plaintiff's claims, sought to invalidate them by proof that there had been no previous discovery of mineral. This was refused by the trial court, and we sustained the ruling, saying (p. 510):

"The patents were proof of the discovery and related back to the date of the locations of the claims. The patents could not be collaterally attacked. This has been decided so often that a citation of cases is unnecessary."

An entry, sustained by a patent, is conclusive evidence that at the time of the entry there had been a valid location and such valid location implies as one of its conditions a discovery, and the decision only went to the extent that this could not be challenged by one who at the time of the entry had made no location and therefore had acquired no tunnel right. There is nothing in this ruling to conflict with the views we have expressed.

It would seem, therefore, from this review of the authorities as well as from the foregoing considerations that, as between the Government and the locator, it is not a vital fact that there was a discovery of mineral before the commencement of any of the steps required to perfect a location, and that if at the time of the entry everything has been done which entitled the party to an entry, to wit, a discovery and a perfected location, the Government would not be justified in rejecting the application on the ground that the customary order of procedure had not been followed. In other words, the Government does not, by accepting the entry and confirming it by a patent, determine as to the order of proceedings prior to the entry, but only that all required by law have been taken.

If, therefore, the entry and patent do not of themselves necessarily determine the order of the prior proceedings, why may not any one who claims rights anterior to the entry and dependent upon that order show as a matter of fact what it was? One not a party to proceedings between the Government and the patentee is concluded by the action of the Government only so far as that action involves a determination. There is a determination by the fact of entry and patent that there was prior to the entry a discovery and a location. Having been so determined, third parties may be concluded thereby.

But it may be said that when the time of a particular fact is concluded by an adjudication or when an opportunity is presented for such an adjudication and not availed of, the time as stated must be considered as settled; that when the plaintiff applied for its patent if there was any question to be made by the defendant of any statement of fact made in the location certificate, or other record, it should have been challenged by an adverse suit. Failing to do so, the fact must be considered to be settled as stated. Undoubtedly, if in an adverse suit the time of any particular matter is litigated, the judgment is conclusive, and if the date of discovery stated in the plaintiff's location certificate had been challenged in an appropriate action brought by the defendant and determined in favor of the plaintiff, there could be now no inquiry. So, when the owner of a lode claim makes application for a patent and the owner of another seeks to challenge the former's priority of right on account of the date of discovery, it is his duty to bring an adverse suit, and if he fails to do so that question will be as to him concluded. Such is the purpose and effect of the adverse proceedings.

Is the same rule also applicable to a tunnel site? This opens up the question of what are the rights and obligations of the owner of a tunnel? And here these facts must be borne in mind. The owner of a tunnel never receives a patent for it. There is no provision in the statute for one, and none is in fact ever issued. No discovery of mineral is essential to create a tunnel right or to maintain possession of it. A tunnel is only a means of exploration. As the surface is free and open to exploration, so is the subsurface. The citizen needs no permit to explore on the surface of Government land for mineral. Neither does he have to get one for exploration beneath the surface for like purpose. Nothing is said in section 2323 as to what must be done to secure a tunnel right. That is left to the miners' customs or the State statutes, and the statutes of Colorado provide for a location and the filing of a certificate of location. When the tunnel right is secured the Federal statute prescribes its extent—a tunnel 3000 feet in length and a right to appropriate the veins discovered in such tunnel to the same extent as if discovered from the surface.

If the tunnel right was vested before a discovery in the plaintiff's lode claim the defendant ought to have the benefit of it. The plaintiff's right does not antedate his discovery, at least it does not prevail over any then existing right. But, it is said, the defendant did not adverse the plaintiff's application for a patent; that its omission so to do precludes it from now asserting a right prior to the date of discovery named in the certificate of location, just as a judgment in an adverse suit involving the question of date would have been conclusive. Is the

owner of a tunnel, who simply seeks to protect his tunnel and has as yet discovered no lode claim, bound to adverse an application for a patent of the lode claim, the lode of which was discovered on the surface? It is contended that the case of *Enterprise Mining Company v. Rico-Aspen Mining Company*, supra, decides this question. But in that case the line of the tunnel did not enter the ground of the lode claim, but ran parallel with and distant from it some 500 feet, and we held that the mere possibility that in the line of the tunnel might be discovered a vein which extended through the ground of the distant lode claim did not necessitate adverse proceedings. Here the line of the tunnel runs directly through the ground of the plaintiff, and the question is distinctly presented whether, in order to protect the right to that tunnel, the defendant was called upon to adverse? Whatever might be the propriety or advantage of such action, the statute does not require it.

Sections 2325 and 2326 provide the manner of obtaining a patent and for adverse proceedings. The first commences: "A patent for any land claimed and located for valuable deposits may be obtained in the following manner." This, obviously, does not refer to easements or other rights, nor the acquisition of title to land generally, but only to land claimed and located for valuable deposits. Then, after prescribing certain proceedings, the statute adds, "if no adverse claim shall have been filed with the register . . . it shall be assumed that the applicant is entitled to a patent . . . and that no adverse claim exists." The next section commences, "where an adverse claim is filed during the period of publication, it shall be upon oath of the person or persons making the same, and shall show the nature, boundaries, and extent of such adverse claims." The section then authorizes the commencement of an action by the adverse claimant and a stay of proceedings in the Land Department pending such action, and adds:

"After such judgment shall have been rendered, the party entitled to the possession of the claim, or any portion thereof, may, without giving further notice, file a certified copy of the judgment roll with the register of the land office, together with the certificate of the surveyor general that the requisite amount of labor has been expended or improvements made thereon, and the description required in other cases, and shall pay to the receiver five dollars per acre for his claim, together with the proper fees, whereupon the whole proceedings and the judgment roll shall be certified by the register to the Commissioner of the General Land Office, and a patent shall issue thereon for the claim, or such portion thereof as the applicant shall appear, from the decision of the court, to rightly possess. If it appears from the decision of the court that several parties are entitled to separate and different portions of the claim, each party must pay for his portion of the claim, with the proper fees, and file the certificate and description by the surveyor general, whereupon the register shall certify the proceedings and judgment roll to the Commissioner of the General Land Office, as in the preceding case, and patents shall issue to the several parties according to their respective rights."

Reading these two sections together it is apparent that they provide for a judicial determination of a controversy between two parties contesting for the possession of "land claimed and located for valuable deposits;" in other words, the decision of a conflict between two mining claims, a decision which will enable the Land Department without further investigation to issue a patent for the land. A tunnel is not a mining claim, although it has sometimes been inaccurately called one. As we have seen, it is only a means of exploration. The owner has a right to run it in the hope of finding a mineral vein. When one is found he is called upon to make a location of the ground containing that vein and thus creates a mining claim, the protection of which may require adverse proceedings. As the claimant of the tunnel, he takes no ground for which he is called upon to pay, and is entitled to no patent. A judgment in adverse proceedings instituted by him (if such proceedings were required) might operate to create a limitation on the estate of the applicant for a patent to the mining claim, and thus, as it were, engraft an exception on his patent. But taking the whole surface the applicant is required to pay the full price of five dollars per acre with no deduction because of the tunnel. The statute provides for no reduction on account of any tunnel. The tunnel owner might be said to have established his right to continue the tunnel through the lode claim after patent, a right which he undoubtedly had before patent, or at least before entry. There is no statutory warrant for placing in a patent to the owner of a lode claim any limitation of his title by a reservation of tunnel rights. In *Deffehack v. Hawke*, 115 U. S. 392, 406, we said:

"The position that the patent to the plaintiff should have contained a reservation excluding from its operation all buildings and improvements not belonging to him, and all rights necessary or proper to the possession and enjoyment of the same, has no support in any legislation of Congress. The land officers, who are merely agents of the law, had no authority to insert in the patent any other terms than those of conveyance with recitals showing a compliance with the law and the conditions which it prescribed."

Other limitations on the full title granted by a patent for a mineral claim are recognized in the statutes. Thus, by section 2339, which is found in the same chapter as the other sections quoted, the one devoted to "Mineral Lands and Mining Resources," it is provided that:

"Whenever, by priority of possession, rights to the use of water for mining, agricultural, manufacturing or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same; and the right of way for the construction of ditches and canals for the purposes herein specified is acknowledged and confirmed."

But it has never been supposed that the owner of any of these rights was compelled to adverse an application for a patent for a mining claim, for they are not "mining claims."

The decisions on the question of the duty of the tunnel

owner to adverse the application of the lode claimant are not harmonious. In *Bodie Tunnel & Mining Company v. Bechtel Consolidated Mining Company*, 1 L. D. 584, Secretary Kirkwood held that a tunnel location was a mining claim and necessitated adverse proceedings to protect its rights as against an applicant for a lode claim, (see also *Back v. Sierra Nevada Con. Mining Company*, 2 Idaho, 420,) while the Supreme Court of Colorado in *Corning Tunnel Company v. Pell*, 4 Col. 507, denied the right of a tunnel owner to adverse the application for a patent for a lode claim where the lode had not been discovered in the tunnel and the discovery shaft was not on the line of the tunnel. Lindley (sec. 725,) referring to the decision in *Enterprise Mining Company v. Rico-Aspen Mining Company*, supra, said:

"In the light of this decision and the one which it affirms, the rule may be thus formulated: Where a lode claimant applies for a patent to a location embracing a lode which has previously been discovered in the tunnel, the tunnel claimant will be compelled to adverse to protect his rights. A right in the particular lode inures to the tunnel proprietor immediately upon its discovery in the tunnel, which right is essentially adverse to the lode applicant; but where there has been no discovery in the tunnel, and it cannot be demonstrated that the lode will be cut by the tunnel bore, there is no necessity for an adverse claim."

Without further review of the conflicting authorities, it would seem that whatever may be the propriety or advantage of an adverse suit, one cannot be adjudged necessary when Congress has not specifically required it. Until the discovery of a lode or vein within the tunnel, its owner has only a possibility. He is like an explorer on the surface. Adverse proceedings are called for only when one mineral claimant contests the right of another mineral claimant.

If the defendant was not estopped by a failure to institute adverse proceedings, then the trial court erred in striking out the parts of the answer in reference to the date of plaintiff's discovery, and the judgment of the Court of Appeals was right.

This conclusion avoids the necessity of any inquiry as to the effect of the alleged estoppel, and the judgment of the Circuit Court of Appeals is affirmed.

### The Wild Mill.

The Wild mill, illustrated herewith, presents what are claimed by the manufacturers to be a series of improvements. A good way to prevent slimes and increase the capacity of a machine is to have the portion of the product that is of sufficient fineness pass the screens. The illustration shows that the feed of the mill is directly on and through the revolving screen, eliminating that part of the product that is of sufficient fineness to pass the finishing screen from the mill, only that part requiring crushing going to the mill. At each revolution the contents of the mill is thrown to the screen and the oversize returns to the mill—a continuous operation, resulting in the fact the mill only operates on that product needing crushing. The revolving ring die, of steel, runs at 150 revolutions per minute, giving a peripheral speed to ring die of 1500 feet per minute. The mullers are placed loose in the mill and weigh nearly 200 pounds each. They obtain their power and speed from contact with the ring die. They have 216,000 square inches of contact per minute. A 5-stamp battery, of 850-pound stamps, dropping at ninety-six per minute, gives 27,168 square inches per contact. One thousand pounds of Swedish pebbles

is caught by the scoop and discharged into the screen. That of sufficient fineness passes, while the oversize goes to the mill with the feed. The screen, which revolves in the opposite direction of the mill, is double. A 6-mesh screen being placed an inch inside the finishing screen, only lets that portion of the material which is of sufficient fineness to pass it and reach the finishing screen, increasing the capacity of the finishing screen as well as protecting it. The machine has only five bearings, two on the main shaft and two on the counter shaft operating the screen and the feeder and the bearing of the revolving screen. A steel cover incloses the machine, which can be removed by removing two nuts. Catalogue showing the details of above mill, with mill plans of recent erections, will be sent on request by the S. H. Supply Co., Denver, Colorado.

### Water Handling Plant.

At the Hampton central power station of the Delaware, Lackawanna & Western Railroad, near Scranton, Pa., is a new water hoisting plant which embodies some features which should prove of interest to metal miners. A shaft has been sunk at a central point to a depth of 460 feet, and all the company's mines in the vicinity are arranged to drain to it. The arrangements for handling water at this shaft are thus described by the *Electrical Review*:

"Water will be hoisted from this shaft by means of two buckets suspended from a hoist tower over the shaft. Around the base of the tower has been built a concrete basin, into which the buckets will be dumped. The water will be piped from this basin to the boiler and turbine station, where such of it as is needed for condensing and other purposes will be utilized. The remainder will be carried on down the hill and discharged into the Lackawanna river.

"The hoist tower is 93 feet from the base to the center of the sheave at the top. It is built of structural steel, roughly in the shape of an A. From the tower are suspended two buckets 6 feet in diameter and 19 feet 6 inches deep. The capacity of each bucket is seventeen tons of water. In the bottom of the bucket are located two lift gates with an area practically equal to the cross section of the bucket. These gates are lifted automatically when the bucket reaches the top, and the water is discharged through the bottom into a spout fitted below the bucket, and which deflects it to either side of the shaft. Each bucket makes a complete round trip in one minute and fifty-five seconds, the total lift being 555 feet.

"The buckets are raised and lowered by means of an 800 H. P. induction motor running at a constant speed of 400 revolutions per minute, driving a pair of drums on which the cables from the buckets are wound. These drums are conical in order to obtain a slow starting speed. The diameters of the drum are 16 feet and 10 feet. The motor is set at right angles to the drums, and motion is transmitted to the latter through a friction clutch and bevel gearing. Band brakes are placed at a number of different points, in order to make a quick stop if necessary."

These buckets are of unusually large size and will

The Wild Mill.

fed to the mill were discharged through a 30-mesh screen in forty-eight minutes. This was done with no more vibration to the machine and with seemingly as much ease as ordinary ore. The revolving or centrifugal motion of the ring die holds the ore to the outside and directly in the path of the crushing members without the use of plows or scrapers. As the ore reaches the top of the mill it

handle a great deal of water if run constantly at the usual speed of hoisting engines, as each of these buckets has a capacity of over 4000 gallons when full.

COPPER SULPHATE has been successfully used in a number of instances in purifying the water of reservoirs within the past year or two, one of which was described herein in the issue of September 3, 1904.

# Mining and Metallurgical Patents.

PATENTS ISSUED MAY 2, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR THE TREATMENT OF ORES.—No. 788,330; R. G. Reilly, Albuquerque, N. Mex.

Apparatus for treating ores, vertical smelting chamber comprising lower and upper sections, lower section being provided with lateral apertures above bottom thereof, air chambers adjacent to lower section and communicating with apertures, air chambers adjacent to upper section, means for forcing cold air into upper and lower air chambers, and agitating devices arranged in upper air chambers and having bars arranged to project through apertures in walls of upper section of smelting chamber.

DREDGING MACHINE.—No. 787,953; A. N. Smith, Chicago, Ill.

In dredger, combination with scow, of turntable upon forward end thereof, pontoons secured to and adapted to move with turntable, main derrick, crane, one end of which is guyed to derrick, opposite end secured to and moving with turntable, scoop or dipper supported by cable passing over one end of crane and suitable mechanism for operating scoop.

COPPER SMELTING AND SEPARATING.—No. 788,589; G. Mitchell, Los Angeles, Cal.

Process of separating siliceous ore, which consists in subjecting raw ore to reducing atmosphere in smelting furnace, fusing it therein, avoiding chemical union of metal with silica in smelting furnace, and withdrawing molten matte.

ORE SEPARATOR.—No. 788,799; C. W. Strong, Ward, Colo.

In ore separator, combination of tank having re-entrant conical bottom portion which is open at upper end, spider supported upon open end of re-entrant bottom, bearing carried by spider, rotatable grinding bell open at bottom and surrounding re-entrant bottom of tank, there being annular space between bell and tank constituting feed space to receive material for treatment, grinding rollers carried by bottom of bell and traveling upon bottom of tank, bottom edge of bell being spaced above bottom of tank to permit of passage therebetween of material under treatment, sides of bell and tank being parallel with top of tank seated above top of re-entrant bottom portion, top of bell being conical and rising above top of tank, and upright drive shaft piercing top of bell with its lower end mounted in bearing and terminated short of top of re-entrant bottom portion.

MINING DRILL.—No. 788,593; F. W. Olecott, U. S. Navy.

Combination of rotary drill; bearing in which drill rotates; box carried by drill; clutch mechanism, rotatably mounted in box and adapted to release from drill and to clutch drill and rotate therewith; manual operating means carried by box and operatively connected with bearing for moving box, and means for rotating drill.

STAMP MILL.—No. 788,729; G. C. Richards, Oakland, Cal.

Stamp mill mortar made in three integral separable sections comprising base with central die recess and surrounding trough, central section in form of hollow inverted truncated cone resting on walls of die recess, central section having screen openings and outwardly extending base flange overhanging.

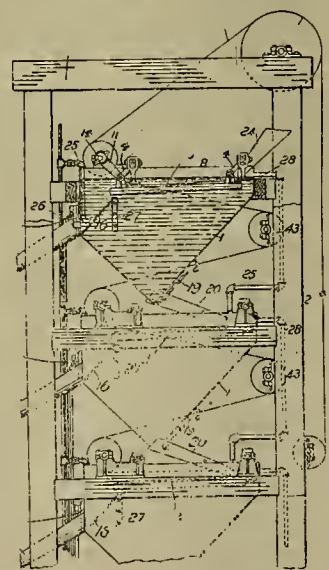

trough, upper section resting on central section and having contracted neck extension and integral hopper which extends into upper portion of central section, sections having interlocking meeting ends whereby they may be assembled and held intact without use of bolts or other securing means.

PLACER MACHINE.—No. 788,737; H. J. Swarts, Denver, Colo.

In placer machine or concentrator, combination with suitable supporting frame, of two stationary pans one mounted above other, lower pan having conical bottom and provided with circular and intersecting radial grooves whereby values or concentrates are directed downwardly to center of pan which is lowermost, upper pan being provided with screen adapted to reject coarser portion of material under treatment, brushes revolubly mounted in operative relation with each pan, brushes of lower pan being inclined to conform with inclination of pan's bottom and adapted to act on material thereon, and brushes of upper pan being arranged above screen and acting on material thereon, and suitable means for rotating two sets of brushes.

MACHINE FOR CLASSIFYING AND SIZING ORES.—No. 788,688; W. E. Wild, Denver, Colo.

In machine for sizing and classifying granulated ores, combination with stationary tank supported within suitable frame, of horizontal swinging screen suspended within and near top of tank by links hanging at all times forward of vertical and having only upward and forward movement in one lateral direction and only downward and backward movement on return, means for swinging screen on links whereby during movements screened material is discharged through mesh down into tank and oversize is discharged over forward end, stationary inclined partition screen crossing tank in path of fall of oversize and secured at side and bottom edges to side and front walls of tank, gated opening in front wall of tank at foot of partition screen for discharge of oversize, and gated opening in bottom of tank for discharge of screened material.

PROCESS OF TREATING FINE ORES.—No. 788,813; D. Baker and W. W. Hearne, Wayne, Pa.

Process of desulphurizing and agglomerating fine iron ores or residues, which consists in eliminating sulphur by means of oxidizing atmosphere at temperature best suited for purpose, and moving mass into temperature which shall cause particles thereof, due to impurities contained therein, to fuse sufficiently to become semi-plastic and sticky, and to agitate mass by revolving it about horizontal or inclined axis.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

Press dispatches state that an ice gorge formed above the town of Fairbanks, the capital of the Tanana section of Alaska, and caused the Tanana river to change its course, leaving the town some distance from the river and the boats at the landing at the time are stated to be lying on the muddy bed of a river which is practically dry. The gold output of the Fairbanks district in 1903 was \$40,000. In 1904 it was about \$400,000, and it is expected that the season of 1905 will see this latter amount largely increased. There are twelve or more creeks in this vicinity which produce payable gravels. These several streams drain a territory of not less than 500 square miles. All of these creeks are within 25 miles of the Tanana river, and a railway now under construction will make Fairbanks one of the most accessible towns in the interior of Alaska. This new and unexpected change in the course of the Tanana river may result in the site of Fairbanks being abandoned for some other location not subject to the caprice of an ice-jammed stream. On page 301 is an illustration of Fairbanks as it appeared the latter part of 1904. The town is not on the main river, but on a slough of the Tanana, navigable for the larger steamers only at high stages of water. There were from 4000 to 5000 people in Fairbanks last summer, and it is said about 3000 remained through the winter. Chena is about 10 miles below Fairbanks on the river. The towns are connected by telephone with the principal producing creeks. In the Tanana district the grades are generally flat and the gravels covered by a thick accumulation of moss, which interferes with prospecting and mine operation. It is thought that mechanical means of handling the gravels will generally give more satisfactory results than hydraulicking, particularly as water is scarce. The gold producing creeks of this region are all small, with rarely over 100 to 200 inches of water. The gravels are from 2 to 80 feet deep, some creeks being deeper than others, and generally frozen throughout the year. The bedrock is usually mica schist—and in some instances this bedrock is payable to a depth of 1 foot to 18 inches. Steam "point" drifting and open pit work are mostly followed in working the ground. In this region ditch construction has thus far been difficult, owing to the heavy deposit of moss and muck. It is thought that the quantity of gold in the gravels, and their extent, seem sufficient to give the camp a permanence like that of the other placer camps in the Yukon-Tanana country. The depth of the deposits has rendered the work of development a slow one. The claims require capital for their development, and the method used most extensively is steam drifting with points. The expense of working the ground consumes probably from one-third to one-half of the output, and the total production from the close of navigation in 1903 to the end of July in 1904 was probably not less than \$350,000. No large quartz veins were observed, and the conditions are apparently unfavorable for quartz mining. The origin of the placer gold is probably to be found in the small quartz stringers which occur generally in the schists.

Manager Hoggatt has started work at the 160-foot level of the Jualin, Berners hay, with sixteen men.

In a recent U. S. Geological Survey report G. C. Martin describes the gold deposits of the Shumagin islands, west of Kodiak and south of the Alaska peninsula. The Apollo Con. mine is near the southern end of Unga island, 3 miles west of the town of Unga. The mine has been yielding since 1891 and claims a production of over \$2,000,000. The ore occurs as a reticulated vein or zone of fracture in a large mass of andesite and dacite, and consists of free gold, pyrite, galena, zinc blende, copper pyrite and native copper. The gangue minerals are quartz and smaller amounts of calcite and orthoclase. The ore body strikes north 43° east, and is, in general, vertical. It is from 5 to 40 feet wide and forms a shoot that pitches northward. The King mine, 1½ mile north of the Apollo, has produced some gold, as has also the Shumagin claims on Baralof or Squaw harbor, 2 miles north. The beach sands near Sand Point, on Popoff island, were washed for gold during the summer of 1904 by from twenty to forty men. All of the gold is found below mid tide and most of it around big stones at the level of low tide. The gold is undoubtedly derived from neighboring mineralized zones in the andesites, which make up the greater part of this and Unga island.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The structural work on the extension of the reduction plant at the Copper Queen smelter at Douglas is going up rapidly. The material is now on the ground and the iron piers and girders are being swung into position. The reduction plant will be as long again as it is now when completed and there will be room for twelve converter stands.—At the Wolverine and Arizona, near Bisbee, the big drift is in 775 feet. The drift from the 300 level is in 200 feet. About thirty men are working at the Wolverine. Water in the shaft is lowering away steadily, due to neighboring pumps. Bisbee, May 9.

#### Gila County.

(Special Correspondence).—D. D. Jayne of Detroit, Mich., acting for the Mascot M. Co., has bought T. D. Morris' claims in the Clark mining district, 28 miles south of Fort Thomas.

Fort Thomas, May 8.

The Payson Milling Co. has been formed by J. W. Boardman, M. McDonald, W. H. Hillgas, R. R. Wilson, J. W. Wentworth and W. C. Colcord, all of Payson, in the Green Valley mining district, to build a quartz mill at Payson.—D. D. Jayne of Detroit, Mich., acting for the Mascot M. Co., has bought from T. D. Morris of

Globe gold claims in the Clark mining district, 28 miles south of Fort Thomas. A mill is to be built on the property.—The Arizona-Colorado Co. at Globe is preparing to resume work and intend sinking their shaft several hundred feet.—It is reported that the Globe-Boston Copper M. Co., which has been idle for some time, will resume operations soon on the Copper Hill.—The Arizona Commercial Copper Co. has put in a Sullivan compressor to run eight drills, and a Vulcan steam hoist.

The April output of the Old Dominion smelter at Globe was 3,082,937 pounds of blister copper, 99.3% fine, obtained from two furnaces running eight days and three furnaces running twenty-two days. With the installation of another furnace, the completion of the concentrator and machinery for moving the ore, Old Dominion will be in a position to increase her production. Three furnaces are still in blast and the average daily output of copper is 100,000 pounds. Preparations are being made for another converter, and the extension of the smelter building and erection of another furnace will follow without delay. The briquetting plant above the smelter is completed, with the exception of laying tracks and providing facilities for handling the briquettes mechanically. At the new shaft the crusher house is finished and construction of the sampling mill is progressing. The new pump of 750 gallons per minute capacity at the twelfth level station is ready to start, and hereafter all pumping will be done through the new shaft. The annual report of the Old Dominion Copper M. & S. Co. for year ending December 31, 1904, shows that the company produced 15,368,147 pounds of fine copper at a total cost of \$1,800,018, from which was realized \$1,941,617. The cost per pound of refined copper at Globe was 14.14 cents, cost per pound of handling 1.05 cent, and the total cost per pound of fine copper, deducting silver and gold values, was 11.19 cents. Smelting cost per ton of ore was \$4.04, and per ton of charge proper \$3.09. The cost of mining per ton was \$4.55, to which must be added pumping, \$1.30, and development, \$0.95, giving a total of \$6.80.

#### Mohave County.

W. A. Walker, superintendent of the Cerbat Mountain M. Co., near Cerbat, reports that the drifts from the bottom of the Vanderhilt shaft shows a continuous body of good grade milling ore. The North Star G. M. & M. Co. has been formed by C. G. Edwards, G. C. Edwards and W. J. Schmitz to work mines near White Hills, with principal office at Albert Lea, Minnesota.—Superintendent C. D. Pickering of the Yucca Cyanide M. & M. Co. at Cedar intends to put in machine drills at the mine and a new plant at the mill.

O. F. Posey of Los Angeles, Cal., manager of the Gold Road M. & Ex. Co. at Acme, will put in a 16-drill compressor to facilitate deeper development. The shaft is down 575 feet. At the fifth level a triplex electric station pump is handling twelve gallons per minute, all that the mine is making. Occasional stulls form all the timbering required. Crushing is done at the shaft and the ore conveyed by mule trains 1200 feet to the 140-ton mill, equipped with six Huntington mills, coarse and fine rolls, plates, sizers and a cyanide plant. A filter press and other improvements are to be added. D. Bosqui is mill superintendent.

#### Pima County.

The Lincoln Con. M. Co. is hauling ore to Tucson. The main tunnel is in 150 feet and the Garcia shaft has been cleaned out.

#### Yavapai County.

(Special Correspondence).—The mill at the Greenwood property, near Prescott, has been started, having been idle on account of the bad weather. E. Greenwood is president and general manager of the property, and has drifted over 1200 feet. The main shaft is down 500 feet and is being carried deeper.—Near the mouth of Yeager canyon, 12 miles southwest of Jerome, the Yeager Canyon C. Co.'s main shaft is down 800 feet and a 600-foot drift has been run on the ledge. Concentrates are being shipped regularly from the 60-ton plant. A new hoisting plant has been put in with a capacity of 1500 feet.

Prescott, May 10.

C. H. McKinley of Kingfisher, Oklahoma, is putting in a large placer mining machine on Lynx creek, near Prescott.—The Oriental M. Co. is unwatering the Postmaster at Providence.—E. E. Greenwood has the new mill in operation upon the properties of the Mount Union Con. M. Co., on Mount Union, Hassayampa district, south of Prescott.—Ed. Campbell has started the mill upon the Geo. Zika properties at Richenhar.—It is stated that Kansas City parties have bonded the Rosalie claims, in Turkey Creek district, and propose to place a smelter on the group.—L. Jackson is working the California and Illinois mines, back of Thumb Butte, near Prescott.—J. A. Conlee has fifteen men developing the Bonnie group, near Prescott. The main shaft is down 170 feet.—It is reported that the Crown King mines will resume work on the tailings pit at Crown King.

The Congress Mines Co.'s cyanide plant at Congress is treating 135 tons of ore daily, the ore coming mainly from No. 5 shaft and from the 1975-foot east and west levels. The shaft from that point to the 2050-foot level is said to be in good grade milling ore. A level is being run at the 2059-foot point. M. Goodloe is the general superintendent. S. Gunn is the mine foreman.—A deposit of nitrate of potash is reported from near Briggs.

Manager G. B. Upton of the Oro Grande, near Wickenburg, is keeping the 10-stamp mill running steadily.—It is reported that Manager S. L. White of the White Gold M. Co. on the Hassayampa, near Wickenburg, will put in a 20-stamp mill when the road is completed to the mine.—The Black Rock M. Co. is completing a 60-ton crushing mill and cyanide plant near Wickenburg. F. H. Perkins is manager.

### CALIFORNIA.

#### Amador County.

The Bunker Hill mill, near Amador, was started up May 1 and it is expected that it will be kept in steady operation from now on.—At the Volcano mine, on the Mokelumne river, in Defender district, operated by cap-

italists of Santa Cruz, a 10-stamp mill is being built. The property is being opened up by a tunnel.—The Orchard placer claim, in Pine Grove, is being put in condition for active operations.—W. F. Detert reports that he has finished unwatering his shaft at his copper mine, near Forest Home, and the workmen are clearing out the drifts. The shaft is 440 feet deep.

#### Calaveras County.

The Chispa Placer M. Co. of Murphys have commenced work on a ditch to carry water from San Domingo creek to work mines of Macaroni Flat.—Superintendent West is taking good ore from the Hercules on Indian creek, near Murphys. E. S. Brown of Los Angeles is experimenting with a new mill on the property.—Work has been resumed at the Big Horn mine, near Murphys.

#### Mono County.

A. E. Vandercook, manager and superintendent of the Southern Belle mine, 5 miles northeast of Laws, will sink the New Year shaft to water level, 200 feet below the present deepest workings. The mill will be enlarged by the addition of at least 5 more stamps. A small electric generator will be put in to furnish power for a hoist at the New Year shaft, and for an air compressor. The vein of gold bearing quartz and limonite runs east and west in a magnesian slate and dips at angle of 35° N. The gold deposits of Mono county are found in a number of districts, the most important of which are Bodie, Jordan and Homer districts. Usually most of the gold ores carry some silver. At Bodie they occur in hornblende andesite and in the Homer district in granite. Most of the work in the gold mines of this county is confined to Bodie and the region about Lundy. There are other sections where valuable properties are idle.

#### Nevada County.

All the buildings, excepting the boarding house and powder magazine at the Star mine, 4 miles from Gaston, have been destroyed by fire. The Star property is being operated by the Gaston Co. The loss will amount to \$3000.

The Erie, Dublin Bay, McCarthy and Holland-Oliver mines, near Graniteville, have been bonned by L. D. Sovereign from the owner, George Meinhart of Nevada City. Work on the Erie, which will first be developed, will commence before July.—The pumps have been started at the Charonnat mine at Canada Hill. The new drain tunnel will be completed in a short time and it will be clear of water, after which development work will begin.—The Talbot mine in Willow valley, owned by George Welch, is to be opened up.

#### Placer County.

The Glenn Con. and Blue Eyes, near Last Chance, are being reopened.

#### Sacramento County.

H. E. Pickett has started a dredger near Fair Oaks bridge.

#### Shasta County.

It is reported that forty out of eighty men have been laid off at the Midas mine at Harrison Gulch. The 10-stamp mill and the cyanide plant are still in full operation.

Manager A. C. Halter of the Original Quartz Hill Gold M. Co., working the Original Quartz Hill mines in the Buckeye district, has returned to the mines and reports that the property will be worked regardless of the action of the smelter people.

#### Siskiyou County.

A. C. Brokaw, superintendent Golden Eagle mine on Indian creek, near Fort Jones, is putting in electric power to develop the property.—It is reported that a shaft is to be sunk from tunnel No. 2 of the McKee mine to develop the property at a lower depth.—The Medina M. Co. are putting in a new concentrator at their mill at Oro Fino. They are also handling ore from the Gardner, Carson and Cradle mines.—Cole & Arnold are putting up a stamp mill to treat ore from the Baker ledge on Indian creek.—The shaft of the New York mine on Indian creek is being sunk 200 feet from the 700-foot level by Superintendent J. B. Scott.—Considerable placer mining and dredging are being done in the county.

#### Sutter County.

R. I. Thomas has bonded 6000 acres of land in the Sutter basin for dredge mining. Preliminary prospecting has been under way for some time past.—H. C. Woodrow has bonded 1100 acres belonging to S. Harris, and has arranged with Moore & Day to prospect the property.

#### Tuolumne County.

A new 4-drill air compressor has been put in at the App mine, at Quartz.—An 18-inch ledge of gold-bearing rock is reported in the shaft at Hidden Treasure, near Soulsbyville.—W. H. Barron is working the Parole, near Soulsbyville, deepening the shaft and prospecting.—On the river near Confidence, H. Gould is building a 5-stamp mill on his mine.

R. B. Lucas is building a 10-ton cyanide plant near the Arbona mill, near Tuttle town, to treat sulphurets from the Arbona and other mines.

### COLORADO.

(Special Correspondence).—The postal authorities, it is understood, have ordered an investigation into the methods employed by certain "get rich quick" mining companies doing business in Denver.—E. L. White, commissioner of mines, is preparing to ship the mining exhibit to Portland for the fair. The exhibit will be along the same lines as that sent to St. Louis. While the appropriation by the State is small, being only \$15,000, yet Mr. White thinks the Colorado exhibit will compare favorably with other States. The \$15,000 is for agriculture as well as mining. The mining department has the advantage of having the material available that was used at St. Louis, so that a fairly good display can be made. The educational department also has the material brought from St. Louis, which will be used at Portland.—When the suits brought by miners against the Mine Owners' Association, in which damages to the

amount of over \$1,000,000 were asked, because of the deportations at Cripple Creek, came up for trial at Castle Rock, in Douglas county, last week, neither the plaintiffs nor their attorney appeared. It is not known what will be done with the cases.

Denver, May 9.

#### Boulder County.

The Wolfstongue M. & M. Co.'s mill at Nederland has been temporarily shut down because of a break in the flume.

#### Clear Creek County.

Trevillion and Cutting, lessees of the Pioneer mine, on Silver mountain, near Empire, have made an arrangement with the Empire Tunnel Co. to operate through the workings of the Gold Dirt property, for the intersection of the Pioneer lode on its dip into the Gold Dirt lode.—At the annual meeting of the stockholders of the Sun and Moon M. & M. Co., Manager R. C. Bonney reported that in 1904 the company had done 3263 feet of development work as follows: Upraises, 1330 feet; drifting, 1700 feet; sinking, 233 feet. During the year there was marketed 21,777 tons of ore and concentrates, for which the company received from the local sampling works \$148,280.88. The mine expenses for the year were \$50,635, while \$50,000 was expended for hauling and milling charges. Manager Bonney was instructed to lease all of the upper workings in the Garden shaft under the tribute system, there being exposed at the present time a full year's ore reserve.—In the Newhouse tunnel, the lateral being driven east to reach the William Penn ore shoot will be pushed. From the surface plant, where an electrically driven air compressor is located, the company has a pipe line of 3000 feet to the Newhouse tunnel level, and is now placing 1300 feet of pipe to the breast of their east drift. This will enable the use of their own power, which at present is being supplied temporarily by the Nowhouse tunnel power plant.

B. and H. Shaver, in their lease on the Dictator mine on Columbia mountain, near Lawson, have struck good ore, a gray copper that assays high in silver.—The Jo Reynolds mine is running full capacity and a night shift has been put to work. The ore is run from the mine to the mill over a gravity tram. It is the intention to change this system to electricity and use an electric motor to handle the cars. E. B. Morton of Idaho Springs is manager.—The Sterling M. & T. Co. is shipping good ore from the Beaver claim on Chicago creek, above Idaho Springs. J. J. Hoban is manager.

The Terrible shaft, near Silver Plume, has been unwatered and repaired as far as the eleventh level.

#### Custer County.

The Toledo at Silver Cliff has been driving for the chimney of ore from the 250-foot level. It is now in 350 feet. G. Raymond is superintendent.—The Custer M. & R. Co. will commence development on the First Colorado and the Livingstone, sinking the shaft on the First Colorado.

#### Dolores County.

Rico is becoming the center of zinc production in Dolores county. The United Rico Mines Co. is shipping large quantities of zinc ore from the new Atlantic Cable shaft, of which H. K. Canning is general superintendent.—The 100-ton Enterprise mill at Rico is to be run by the Durango Leasing Co.—The Buckhorn—twelve claims adjoining the United Rico's property on the south and the Union Carbonate mine on the north—has been bonded and leased by Chicago, Ill., capitalists, who will run a tunnel to connect with the shaft workings, through which the property will be operated. The resumption of work, backed by capital and an open market for the zinc and other ores of Rico, marks the opening of a new era for the Dolores country. Fifteen years ago the mines of Newman and neighboring hills were among the most productive in the State. After the panic of 1893 there was a gradual decline, which ultimately suspended work on a great number of properties. The geological conditions were not as well understood as they are now. The rapidly falling price of silver disheartened those whose ores carried little gold. Certain of the larger veins developed such quantities of zinc, for which there was no market, the operators could not proceed; therefore, one after another shut down.

#### Gilpin County.

The Kirk mine in Leavenworth gulch, south of Central City, was twenty-five years ago, according to the Denver Post, a producer of high-grade pitchblende. The operators who worked it under a lease, after having sunk the shaft 125 feet and shipped quantities of this ore, being carried away by the Leadville excitement then prevailing, ceased work. The Kirk was idle from that time until the spring of 1904, when the demand for uranium for scientific uses induced L. G. Nesmith of San Jose, Cal., to secure a bond and lease on the property. He unwatered the shaft, cleared out the debris and broken timbers, made complete repairs and put in machinery, employing as foreman W. J. Thompson. The shaft was deepened 50 feet and drifting to the east has disclosed a vein of pitchblende 10 inches wide. He shipped three tons last month and has in Denver four tons of high-grade ore. In process of mining he has extracted and raised 100 tons that will average 4%.

The shaft is to be sunk 50 feet deeper.

The Norway-Colorado M. Co. are developing their claims in northern Boulder park district under the direction of J. Iverson.—It is reported that work is to be resumed on the Good Springs tunnel on the south side of Boulder park.

#### Gunnison County.

The Augusta Metal M. Co. has men working on the Augusta, above Crested Butte, in the Elk mountains. The tunnel to the ore bodies from the Pittsburgh side of Augusta mountain has been completed.—The Taylor Park M. Co., working the Enterprise mine in Tellurium gulch, in the Tin Cup district, is meeting with success.—A big find of ore is reported as having been made on the Baxter group, owned by Baxter, Witzke and others, in Grant gulch, ½ mile south of the Camp Bird.

#### Lake County.

The Gilt Edge property on the south side of Iron hill,

Leadville, has been sold to the S. M. P. M. Co. for \$200,000. J. H. Crawford, Mendota, Ill., president; G. F. Burtch, Leadville, vice-president; H. A. Rupp, Leadville, secretary. There are two shafts on the property, down 600 feet, and it is the intention of the new company to sink both deeper so as to open up the sulphide zone.

The new work at the Yak tunnel at Leadville—that of driving a lateral into Iron hill—is important to owners of property on the trend of the lateral, as it will drain the hill, allowing the sinking of shafts deeper at a nominal cost. The lateral starts 2300 feet from the mouth of the tunnel, cutting through the Silver Cord ground, thence through Colorado No. 2, thence to the Tucson, and finally to the Belgian, a distance of over 2000 feet. The Tucson shaft is being enlarged and will take two months to complete; then the shaft will be sunk 350 feet deeper, making it 950 feet deep. The lateral will have reached the Tucson before the shaft will have gained the necessary depth; the hill will be drained and the Tucson will have no water to lift. The Tucson is the extension of the Moyer, and the diamond drill has proved that the Moyer ore shoot is in this property to as great extent as in the original.

A strike of high-grade telluride ore is reported in the Manhattan M. & P. property in Willis gulch, near Twin Lakes. O. P. DeFord is president and G. W. Herrington is manager.

#### San Juan County.

The Crispin M. Co., under the management of E. Clemmons, will start work on the Crispin group, near Eureka.—W. H. Taggart is working the Octopus claims, in the south fork of Eureka gulch, 10 miles north of Silverton.—J. Klumartin will resume operations on his San Pedro claims, in Whitehead gulch, near Silverton.—The Auburn Con. G. M. Co. on Tower mountain, near Middleton, has made arrangements for an 8-drill compressor, drills and an 80 H. P. boiler. A new boarding house will be built as well as new bunk houses, machine shop, blacksmith shop and ore house. Work on the property at present is being confined to a tunnel, in 200 feet, being driven to cut the Auburn vein.—Work on the Bullion King property in Porphyry hasin has been resumed by Manager A. J. Durand.—A good strike has been made on the Bald Eagle claim of the Eagle-Klondike group on Cement creek, opposite the Yukon tunnel, 3 miles north of Silverton. The property is owned and operated by Carver & Butler.

J. W. Doolin, in charge of the Mammoth tunnel of the Stony Pass M. Co., near Silverton, reports that the tunnel is in 1225 feet.

#### Summit County.

G. C. Wortman, superintendent Burmah M. Co. at Wortman, near Climax, reports that they are fixing up the old mill to save all values in their silver-lead-zinc ores.—Work is to be started on the Sallie Barber under direction of T. Keith of Breckenridge.—The Senator tunnel, near Breckenridge, is in 1100 feet and has cut 3 ledges. M. M. Howe is manager.—The French creek tunnel is in 850 feet under Mt. Baldy. The French creek tunnel under Mt. Baldy, near Breckenridge, is in 850 feet. Manager M. G. Evans intends to drive 2500 feet before working the ledges.

#### Teller County.

G. L. Keener, leasing on blocks 54 to 60 of the Globe hill property of Stratton's Cripple Creek M. & Dev. Co., is putting in an air compressor in the Chicago & Cripple Creek tunnel that will furnish the power for crosscutting his lease at a depth averaging 800 feet.—The Elkton Con. Co. has cut the Walter vein at the 900-foot level.—The Granite shaft on Battle mountain is to be put down to the 1200-foot depth and a 65-foot gallows frame is to be put up.—Talbot and associates has started sinking the Little Zoe shaft on Beacon hill from the 550-foot to the water level.

### IDAHO.

#### Blaine County.

The North Star claims, on the North Fork of Wood river, have been bonded and leased to the Hailey Mining Bureau, which will begin work before July 1. The ore carries considerable zinc.—Superintendent H. J. Allen of the Big Lode Co. near Hailey, has the new tunnel in 140 feet. They hope to strike a continuation of the Minnie Moore vein.

#### Boise County.

Work has been started on construction of a dredger at the junction of Granite and Fall creeks, near Placerville, for Blaine & Nye.

#### Idaho County.

The Crooked River M. & M. Co. have thirty men working in the mine and mill at Oro Grande. They expect to commence milling ore soon.—W. C. Brower has men at work on the Bison property on Rock creek, near Oro Grande.

#### Kootenai County.

At the Farmer Jones, Pine creek camp, near Priest River, G. C. Sutton is driving a 400-foot tunnel to tap the main ledge.—Pugh & Secord are driving a tunnel on the Camp Bird group.

#### Owyhee County.

Manager Orford of the DeLamar Co. is developing the Rooster Comb property, 9 miles north of DeLamar and 3 miles west of Share's Station, on Reynolds creek.—M. H. Jacobs has miners at work on the King mine, in the Rooster Comb district on Sucker creek, which he has bonded from T. W. Jones of Boise.

#### Shoshone County.

H. W. Ingalls, secretary of the Copper King Co. of Mullan, says that a wagon road is to be built from the mine to Burke.—Work has been resumed on the O. K. group in Government gulch, near Gardner, extending the Mabel tunnel.

#### Washington County.

The mill of the Gold Coin M. Co. has been temporarily shut down by the breaking of a casting in the crusher, which cannot be replaced until the roads are opened up. The mill and cyanide plant has a capacity of 100 tons

and is said to have made a saving of 93%. The ore after passing through the crushers is reduced by rolls to 16 mesh and leached for forty-eight hours. The company is taking ore from the Summit vein and the Maid of Erin vein. They have started a drainage tunnel that is expected to facilitate mining. They have been working forty men all winter.—The Iron Springs Con. M. Co. at Iron Springs has been working forty men during the winter.

### MISSOURI.

#### Jasper County.

Jeffries & Co., who have a lease on the Showmaker land southeast of Joplin, have made a rich strike of free ore at a depth of 110 feet.—The Waymire Bros. have opened up a prospect on the Pearl ground on the Henry Weymann lease, near Joplin.—Judge Phillips' decision that mine operators are responsible in case of cave-ins has been affirmed by the Federal Court of Appeals. The case in question was that of S. Duffield Mitchell v. the Big Six Development Co.—The Gertrude M. Co., composed of W. H. Robeson, G. W. Carter and others, have opened up a mine of jack and lead on the Colorado M. Co. lease at Tuckahoe.—G. L. Florristall of Boston will resume operations at the Florristall & O'Donald mine on the Missouri Zinc Fields land, near Webb City.—The Calumet Lead & Zinc Co., operating on the Horton land near Webb City, has opened up a new body of ore.—H. J. Vancill and B. M. Robinson, both of Joplin, have opened up high-grade ore in the 180-foot level on their mine, near Prosperity, and intend to put up a 125-ton mill.—Patton & Dodge have started their new electric mill, near Prosperity.

#### Lawrence County.

The double lift pumps at the Spring River mine at Stott City have been started.—R. Stephens has rebuilt the old Spring River mill at Stott City.—The Three C crusher has been moved to the McFarlane plant at Stott City by Superintendent F. Harper.

#### Newton County.

The Sunny South Co., composed of O. Bishop, J. Carlyton, L. P. Kelley, H. Chester and S. Hudson, are sinking a new shaft west of Granby, and are down 90 feet.

### MONTANA.

#### Deer Lodge County.

Judge W. H. Hunt in the United States Circuit Court has issued an order directed to the Anaconda and Washoe companies to show cause why a preliminary injunction should not issue against the operation of the Washoe smelter at Anaconda. The order was issued upon the application of F. J. Bliss of Emmett, Idaho, who owns land in the Deer Lodge valley, and many other neighboring farmers who allege their property has been deteriorated in value by smoke and fumes from the big smelting plant. The Bliss petition for the order alleges that property to the value of \$2,000,000 has been damaged. The order to show cause is made returnable June 5th in Helena.

#### Jefferson County.

(Special Correspondence).—The La France Copper Co., a Heinze enterprise, is to take over the Lexington mines, on which Heinze has a lease and option, and the smelting plant of the Basin & Bay State M. Co. at Basin. The Lexington mines are old and worked-out silver properties, which lately have shown indications of turning into copper mines at depth.

Basin, May 8.

#### Madison County.

It is reported that the Watseca M. Co., at Rochester, have closed their mill.

#### Missoula County.

The Orlando M. Co. has been formed to work claims in the Mountain Home mining district.

#### Silver Bow County.

(Special Correspondence).—T. F. Cole and other men interested in the new North Butte Copper Co. have been inspecting the Speculator mines, which are about to be turned over to the new corporation. Negotiations are pending for several other properties.—R. Baggeley, manager of the Pittsburg & Montana Copper Co., says the only reason the company's new process smelter is not in operation is because the development of the mines has been delayed by a deluge of water. The workings of the mine are still flooded and the new electric pumps are not working satisfactorily.—W. A. Clark has purchased the half interest of his partners in the Black Rock mine, in the North Butte district, for \$50,000. The mine is at present worked by the Black Rock Co. under a three years' lease.

Butte, May 9.

The new shaft on the Goldsmith mine, north of Walkerville, has been sunk 200 feet; thirty-five men are at work.

### NEVADA.

#### Douglas County.

It is reported that extensive development is to be commenced at the Longfellow mine, 30 miles south of Carson, under the direction of E. Carman.

#### Humboldt County.

It is reported that the Golden Eagle M. Co., which has been operating on a bonded mine in New Central and been working the property, put in a mill, cyaniding plant and other buildings, under the superintendence of M. D. Smith, has shut down.

#### Lincoln County.

B. F. Lewis of the Parallel G. M. Co. will resume sinking in the main shaft, which is down 165 feet, and has ordered a 15 H. P. gasoline engine.—T. O'Connor of Juniper camp, 20 miles south of Searchlight, announces that he will have his new mill in operation within a week. The first ore to be run will be from the Chiquita mine, whose working shaft is down 230 feet.—The Black Hawk M. Co. of El Dorado is working fifteen men. The new hoist is in place on shaft No. 2 of the Buster mine and sinking has begun. The shaft will be carried

6½x9½ feet in size. An assay office has been built and quarters for Superintendent Gresh are going up. Development work is also being done on the Rand and the Black Hawk mines.

#### Lyon County.

The Davidson & Lockwood quartz mill on Missouri Flat, near Yerington, is running. The mill has a capacity of seven tons a day and is running on ore from the Davidson & Lockwood mine. — E. W. Davies, who with G. Barrett has been developing a mining claim on East Walker, near Yerington, reports that the mine will produce ore sufficient to keep a small mill running, and is figuring on building a mill near the mine and putting in a 10 H. P. gasoline engine to operate the mill and hoist.

#### OREGON.

The text of the new law regarding a date label on explosives states that all blasting powder and fuse shipped into Oregon for use, or manufactured in Oregon for use in Oregon, shall have stamped or printed upon the outside of each of such original package, box, case or wrapper the date of manufacture of the contents thereof. Whenever any blasting powder shows a state of disintegration or decomposition sufficiently so that it remains in a soft condition in a temperature of 42° F., or is in a state of crystallization, which is revealed in some portions being in a hard condition and surrounded by other portions in a soft condition, it shall be deemed to be bad and dangerous powder, and its sale and use is hereby prohibited. Whenever any fuse shows by its appearance to have been overheated, or if it is in a hard and brittle condition, which is seen by breaks and cracks in the wrapper around the outside of the fuse, the same shall be declared unfit for use and sale, and its use is hereby forbidden. It shall be unlawful for any person or persons to sell or exchange or to offer or expose for sale or exchange, or to have in possession for use by his or any of their employes, any blasting powder or fuse which has not been stamped or printed upon as required in Section 1 of this Act, or any blasting powder of which the sale and use is prohibited by Section 2 of this Act, or of any fuse declared to be unfit for use as prohibited in Section 3 of this Act. Whoever violates any of the provisions of this Act shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than \$10 and not more than \$100 for each offense. This law is now operative.

The law regarding amended location notices states: If at any time the locator of any mining claim heretofore or hereafter located, or his assigns, shall apprehend that the original notice of location of said mining claim is defective, erroneous, or that the requirements of the law had not been complied with before the filing of said notice, such locator, or his assigns, may post and file for record in the manner now provided by law, an amended notice of the said location, which shall relate back to the date of the original location; provided that the posting and filing of such amended notice of location shall not interfere with the existing rights of others at the time of posting such amended notice of location.

#### Baker County.

Owing to the storms and bad roads, the Imperial mine at Cable Cove is unable to deliver its ores to the Sumpster smelter. Snow has fallen in Cable Cove, and has drifted in places to a depth of 20 feet. — The Red Chief, adjoining the Imperial group, is ready to start work. — The Alpine at Cable Cove is reported to have shut down temporarily. — The E. & E. shaft at Bourne is free from water and work on the lower levels is now carried on without interruption from that source. Concentrates are being hauled here to the smelter daily from the mine. The mill is kept steadily crushing ore. — The Victor crosscut, adjoining the Tabor Fraction at Bourne, is in 750 feet, and is said to have cut a 3-foot pay shoot.

#### Josephine County.

The Homestake mine, ½ mile west of Woodville, is shut down after a short run with the 5-stamp mill. It is stated that five stamps are to be added and that electric power is to be used.

#### Lane County.

(Special Correspondence). — Manager W. B. Dennis of the Black Butte quicksilver mine, south of Cottage Grove, has completed his new furnace and reports it as successful. — W. H. Winnings of Illinois has been at the Twin Rocks property at Bohemia making plans for summer work with Manager Lewis Hartley.

Cottage Grove, May 9.

#### SOUTH DAKOTA.

##### Lawrence County.

The Consolidated Power & Light Co. has been formed at Deadwood to supply light to Deadwood and Lead and to furnish power to the various mills throughout the Black Hills. — One of the mills now receiving its power from the Consolidated Power & Light Co. is the Gilt-edge Maid. This mill has been overhauled and improvements made in its method of treatment. It is now treating over 100 tons per day. — It is stated that the 120-stamp mill of the Branch Mint Co. will be in operation by September 1 and that in the mines a large force will be employed. The company's ground is located in the Bare Butte district, at Galena. Attached to the stamp mill will be a complete cyanide plant for the re-treatment of the tailings. Mining will be done from the Hoodoo shaft, at which there has been placed five Gates crushers, and the ore will be dumped into the crushers as it is hoisted and from there into storage bins, from which it will be drawn as wanted into cars for transportation to the mill. J. Hardin is general manager. — The Extreme M. Co., 2 miles northeast of Custer City, is putting in a cyanide plant for the re-treatment of the tailings and a power hoist and air compressor, drill and improved machinery. They intend to connect the milling plant and mine with a tramway. — A switch is being built to the milling plant of the Victoria M. Co. on Spearfish river at the mouth of Squaw creek, in the Ragged Top district, for the delivery of heavy machinery, building material and other supplies. W. M. Glass of Omaha has been made managing director. Work on the 240-ton mill has been started. — Superintendent L. L. Allen of the Lucky Strike M. Co., 9 miles southeast

of Lead, says that they intend to build a large stamp mill on Elk creek. At present there is no work doing at the mines, and will not be until the weather settles and the roads dry up. — It is proposed to build a cyanide plant on the Richmond-Sitting Bull property in the Galena district. C. B. Harris, who was superintendent, has gone to New York City to confer with Henry Earle, the owner. When the property was gutted of its rich smelting ores medium grade ores were left standing, and it is this material it is now proposed to run through the cyanide process.

#### UTAH.

##### Salt Lake County.

Manager W. C. Orem of the Utah-Apex at Bingham has put in a new compressor to facilitate work on the 3000-foot tunnel being driven to develop the ore body.

Furnace No. 1 at the Yampa smelter, at Bingham, has been changed to correspond to furnace No. 2, by increasing the number of tuyeres, thus increasing the blast and the smelting capacity. The new waste heat boiler, the first in this State, is in operation, and its work is said to be effecting a saving in fuel. — Superintendent Taylor of the Bingham Central reports the upper tunnel, which is being driven to strike the Red Elephant vein, is in 150 feet. The Jeff Davis tunnel, which is being extended to open up the Bonham vein, is in 500 feet and seams of iron sulphides are coming in. It is figured that the vein is 100 feet away. — At the Bingham-New Haven, Superintendent Gillan is cutting a station 2000 feet from the mouth of the tunnel, where a 30 H. P. hoist will be put in and a winze sunk. — At the New England, Manager Adkinson reports that the Timber vein, which was cut by a crosscut last fall, has widened to 10 feet between walls. The Nast vein, at the face of the workings, 1700 feet from the mouth of the tunnel, is 5 feet between walls. The mill capacity has been doubled by putting in a new crusher, and both jigs will be placed in commission. — At the Phoenix mine, Manager Gebhardt announces that a new tunnel will be started, 300 feet below the present tunnel, and driven 2000 feet to a connection with the ore bodies. A winze will be sunk on the big ore body opened through the present tunnel, to a depth of 300 feet, where it will be connected with the new tunnel. An electric hoist will be put in at this winze. — The new tables and crusher for the remodeled Kempton mill have been put in. A new ore bin is to be built back of the mill.

Superintendent A. O. Jacobson of the Columbus Consolidated mine of Alta says it will take until July for the teamsters to remove the congestion at the bins, both at the mine and mill, with the production kept going ahead as usual. The road has been broken through to the mine.

##### Sevier County.

B. T. Ashby, working the Aldebaran, near Marysval, will put in an air compressor before any more work can be done, as work has been stopped by the bad air. He has been drifting from the bottom of a shaft 100 feet below the tunnel.

##### Tooele County.

T. Marrion, superintendent of the Flying Dutchman at Sheeprock camp, near Eureka, has the shaft down 175 feet on the vein. A roasting furnace is to be put in.

##### Utah County.

H. J. Kruse, superintendent of the Bogg mine in American Fork canyon, has returned to that property. — G. Summerville, manager of the Blue Rock mine, operated by the Pacific G. M. & M. Co., is continuing work commenced last fall.

#### WASHINGTON.

##### Ferry County.

C. H. McNaughton, of the Belcher M. Co., near Republic, says that the Belcher Company had decided on building a narrow gauge railway from the Belcher mine to connect with the railroads and that ore bins would be constructed at convenient railway sidings; that the ore from the mine will be delivered from self-dumping cars to the bins and delivered thence to the broad gauge cars for transportation to the smelters. — Work has been started on the 115-foot level of the Ben Hur mine, near Republic, and a drift is being driven northward on the vein. The working force has been increased to eighteen men. F. H. Anderson of Detroit, Mich., is assaying for the company.

##### Snohomish County.

The Sultan Placer M. Co. has dug 1400 feet of their ditch, leaving 1750 feet yet to be excavated. Flood gates have been put in and the company is awaiting high water to carry out loose rock in the ditch, which will save \$700 worth of labor. If the expected high water does not come, a temporary dam will be thrown across the stream to raise it high enough to throw water into the ditch.

##### Stevens County.

It is reported that tungsten in considerable quantity has been found at Cedar canyon and Deer Trail camp. Superintendent Blevins of the Copper King mine, near Chewelah, has put additional men in the mine, also men repairing the road between Chewelah and the mine, getting the road in shape for the traction outfit.

#### FOREIGN.

##### AUSTRALIA.

(Special Correspondence). — In 1904 there was an increase of silver production in New South Wales, the exports from that State reaching the value of £2,065,540. The two leading silver producing States are New South Wales and Tasmania. The principal supply in the former is obtained from Broken Hill, 925 miles northwest of Sydney, near the South Australian border, the nearest port being Port Pirie, in the latter State, where smelting operations are conducted on a large scale. Broken Hill forms part of the Barrier district, so called from a series of low hills known as the Barrier Range, and including Silverton, Thackaringa and other argentiferous localities. The Barrier silver field extends over 2500 square miles and was discovered in 1883 by a boundary rider named Rasp. At that time hardly anything was known of the country, there being no roads and

little population, but at present Broken Hill has a population of 28,000. The leading mine, the Broken Hill Proprietary, has produced from the commencement of mining operations in 1885 to the middle of 1904 7,134,526 tons of silver and silver-lead ores, from which were obtained 124,552,679 ounces of silver and 663,423 tons of lead, valued in the London market at £26,896,000. In Tasmania the principal silver fields are in the western and north-western districts, the largest output being from the Mount Lyell mine, where the metal is found with copper. Silver is found in various parts of Queensland, mostly associated with other metals, the principal mine being at Texas, in the Stanthorpe district. There are no silver mines in Victoria or Western Australia, but this is more than compensated by their auriferous richness. The metal is, however, occasionally found associated with gold. In 1903 the value of the Victorian silver thus obtained was £2280, that produced in Western Australia being valued at £19,153. Although the Barrier silver field approaches very closely to the South Australian border, it does not cross it, hence the silver production of that State in 1903 reached a value of only £2071. The great difficulty hitherto experienced in the silver mining industry has been the want of some cheap and effectual method of treating refractory ores. Much has been done in this direction at Broken Hill, and practical men entertain an opinion that within the next few years the cost of extracting the silver and dealing with the other metallic contents of the ores will be reduced fully one-half, if not more. The total value of the silver raised in the Commonwealth to the end of 1903 was £40,124,145, as follows: New South Wales £35,283,159, Tasmania £2,872,276, Queensland £923,725, Victoria £864,276, South Australia £140,441, and Western Australia £40,425. There are rich silver deposits in the Northern Territory of South Australia, but up to the present none have been worked to any extent. In one locality extensive silver lodes have been discovered, carrying 100 ounces of silver and a large percentage of lead to the ton. Lodes of silver-bearing ores have also been found near the Mary river running from 50 ounces to 300 ounces per ton. Most of the lode silver comes from galena, which, as a rule, is very rich in the metal.

Sydney, April 17.

#### CANADA.

##### BRITISH COLUMBIA.

###### Boundary District.

The Jewel Gold Mines, Ltd., in Long Lake camp, are being pumped out preliminary to examination by the Le Roi 2 Co., which has an option on them. The properties consist of the Jewel and the Denoro Grande. The development consists of a two-compartment shaft 330 feet on the dip of the ledge. Three levels have been opened up.

For the week ending May 6 ore was sent out from the Boundary mines as follows: Granby mines to Granby smelter, 11,725 tons; Mother Lode to B. C. Copper smelter, 3636; Brooklyn to Montreal & Boston smelter, 2940; Rawhide to Montreal and Boston smelter, 750; Mountain Rose to Montreal & Boston smelter, 188; Dominion Copper Co.'s Brooklyn and Stewindler dumps to Trail smelter, 150; Oro Denoro to Granby smelter, 100; Sulphur King to Granby smelter, 33; Providence to Trail smelter, 20; Last Chance to Montreal & Boston smelter, 55. Total for week, 19,597 tons; total for year, 325,085 tons. The three district smelters treated ore for the week as follows: Granby smelter, 11,647 tons; B. C. Copper smelter, 3770; Montreal & Boston smelter, 3973. Total for week, 19,390 tons; total for year, 330,165 tons.

The long tunnel on the Golconda, Deadwood camp, is in 375 feet. — The Twin claim, Greenwood, has been bonded by R. Smalles and others from R. Wood & Co. — A new slag hauling locomotive is in use at the Granby smelter, making six steam locomotives now in use at mines and smelter. — The tunnel being run on the Gold Bug to crosscut the ledges is in 125 feet. A steam drill is being used and the contract calls for 300 feet of tunneling. — A report from Grand Forks says that at a general meeting of the shareholders of the McKinley Mines, Limited, owning the McKinley and Hanna mineral claims in Franklin camp, a working bond for \$150,000 has been granted M. M. O'Brien, Jr., of New York, as trustee for Boston and New York capitalists.

###### East Kootenay District.

The output of the St. Eugene mine in Fort Steele division for April was 3200 tons, or an average of over 100 tons per day. Six muckers employed at the St. Eugene mine pleaded guilty and were each fined \$2.50 and costs for violating the eight-hour law. The case was tried before L. Thompson, justice of the peace. On the 8th and 9th of March these men were working in the shaft level. There was a rush of work and they were asked to work overtime in order to have the muck cleared away for the shift following. The matter was reported to the mine inspector, who in turn caused the arrest of the men. There is also a heavy fine for a company violating this law, and the case against the St. Eugene company will come up for trial later on.

###### Northwest Kootenay District.

From Poplar it is reported that the Great Northern Co. will put in a stamp mill this summer and go ahead with the work on the Lucky Jack. — The Spyglass Co. on Poplar creek is resuming operations. — The Primrose and Old Gold are restarting development work on a large scale. — The Guinea Gold, on the summit of the range, will be started as soon as the snow clears off. — The Triune Co. has announced the building of a tramway and the subsequent erection of a concentrator for the treatment of its low-grade ore. — More men are being put to work upon the Nettie L. and Silver Cup, 8 miles from Ferguson, and as a further evidence of activity the promoters of the tunnel scheme to crosscut the leads of this portion of the Lardeau district at depth and finishing up preliminary proceedings anterior to active work. — Near Trout lake the Winslow is being opened by B. White.

###### Rossland District.

C. F. Jackson of the Reddin-Jackson Co. of Spokane says that a Spokane syndicate is getting ready to begin operations on the Iron Horse mine on Red mountain. G. S. Waterlow, director of the Le Roi, J. Cronin,

manager of the War Eagle-Center Star, A. J. McMillan, general manager of the Le Roi, and W. H. Aldridge, manager of the Trall smelter, have been at Russland conferring as to the proposed amalgamation of the Center Star, War Eagle, Le Roi and other properties.

The shipments for the week ended May 6 were as follows: Le Roi, 2350 tons; Center Star, 1767; War Eagle, 1230; Le Roi No. 2, 290; Le Roi No. 2 (milled), 600; White Bear (milled), 300; Jumbo, 300; Spitzee, 90. Total for the week, 6627 tons; and for the year, 121,714 tons.

Slocan District.

It is reported that as soon as the present leases on the Whitewater mine run out, S. S. Fowler will operate the property in the interest of the company.—The Ruth is expected to resume after a shut down of many months. Men are loading and shipping the zinc concentrates at the mill to the Kaslo sampler.—The upper workings of the Queen-Dominion, formerly the Queen Bess, have been leased to L. Savage, Wm. Fogg and M. McGuigan.—J. W. Powel and E. Erickson have purchased the entire holdings of other parties who were interested in the Silver Glimmer mine at Bear lake, and intend to work the property on a partnership basis.

Quebec.

J. Ohalski, Inspector of Mines of the Province, reports the mineral production of Quebec for the year 1904 as follows: The production of metals included twenty ounces gold obtained from prospecting operations in various streams. No systematic operations were carried on in the Beauce district during the year. The output of pig iron was 11,121 tons, made in the charcoal furnaces at Radnor and Drummondville. In making this iron there were used 24,857 tons of iron ore, 3003 tons limestone and 1,446,607 bushels charcoal. Of the ore used, 16,132 tons were hog ore from Radnor and neighborhood, 200 tons hematite from Bolton township, Quebec, 8705 tons from Ontario. The production of minerals for 1904 is reported as follows:

	Quantity.	Value.
Hog iron ore, tons	16,152	\$51,884
Titaniferous iron ore, tons	100	300
Chrome ore, tons	6,429	71,499
Copper ore, tons	23,729	95,000
Asbestos, tons	35,479	1,186,755
Asbestos, tons	13,149	13,149
Mica, pounds	301,565	\$5,924
Other calcined, tons	1,500	18,825
Graphite, tons	25	2,300
Phosphate, tons	730	4,590
Total		\$1,582,341
	Quantity.	Value.
Slate, square	5,277	\$23,247
Flagstone, square yards	3,000	2,550
Granite		120,000
Cement, barrels	23,450	50,450
Lime, bushels	1,000,000	140,000
Brick, No.	130,000,000	625,000
Building stone		530,000
Total value		\$1,491,047

The total value of all products, including the gold, but not including pig iron, was \$3,023,568. The value of the pig iron was \$256,376, which would bring the total up to \$3,279,944. The number of men employed was 5067; their average wages amounted to \$1,359,520. There were four men killed and four seriously injured during the year. This shows 0.79 killed per 1000, the total casualties being 1.58 per 1000 employees. Experiments continue to be made with the black magnetic sands of the north shore of the St. Lawrence, but no commercial work has been done. The titanic iron ore reported was from Kenogami. No work was done on the manganese ore deposits of the Magdalen islands. Assays of this ore gave from 50% up to 64.6% manganese. The other came from St. Malo, near Trois Rivières, where two companies are at work. Chrome-ore mining was active during the year, two companies being at work. The copper mining industry was also active. The Eustis M. Co. is putting in a large electric plant, operated by water power from the Conticooke river. This will enable the company to extend its operations. Asbestos mining is being extended in the Thetford and Black Lake districts. The American Asbestos Co. was organized and is building a large mill. Several companies are operating in mica. The shipments in detail were as follows: 1x1-inch sheets, 3200 pounds; 1x2-inch, 46,680 pounds; 1x3-inch, 100,855 pounds; 2x3-inch, 88,550 pounds; 2x4-inch, 36,450 pounds; 3x5-inch, 14,350 pounds; 4x6-inch, 8050 pounds; 5x8-inch, 3400 pounds; total, 301,565 pounds. The business has been injured by the use of various insulating compounds in which scrap mica is utilized. Only one graphite company was at work. There was no mining of harytes or gypsum. One company made cement and another built works, which were started in January of this year. The Canadian Gas & Oil Co. is boring for gas in the Beauséjour range and has a good outfit. There are small wells in the Province yielding natural gas at several places, among others at Yamachiche, Louisville, St. Barnabe, Ste. Genevieve de Bastian. Some has also recently been discovered at St. Pierre les Bequets. At these places slight borings have been effected by hand through the clay and the gas issuing from the gravel beds is used for heating and lighting houses. Experiments in preparing peat are being made at Farnham, but there has been no commercial production.

MEXICO.

The Chihuahua Enterprise says the new Mexican gold coins of \$10 and \$5 will be as follows: On the obverse the national coat of arms, the inscription, "Estados Unidos Mexicanos," and ornamental scroll work. On the reverse, the bust of Hidalgo, with inscriptions showing the denomination of the coin and the year it was struck. The silver dollar will remain the same as at present on the reverse, but on the obverse it will display the inscription: "Estados Unidos Mexicanos." The silver 50, 25 and 10-cent pieces will have the same obverse as the gold coins. The reverse will display the denomination in large figures followed by the word "Centavos" (cents), and will have a Phrygian cap with rays and a wealth of laurel and oak. Along the milling of the 50-cent piece the words "Independencia y Libertad" will be hollowed out. The milling of the 20 and 10 cent pieces will be straited only. The nickel coins will have an obverse practically the same as the gold coins. The reverse will have an Arabic "Five," the word centavos,

the date of coinage, all enclosed in a grecque imitating the Aztec calendar. The bronze coins: Obverse like gold coins; reverse, the figure indicating the value of the coin, forming with letter C (centavos) a monogram, all surrounded by a laurel wreath. All the coins will have on the reverse the initial of the mint at which they were coined.

Jalisco.

The Amparo M. Co. of Ezatlan intend to build a 100-ton reduction plant as soon as experiments on the ores are completed. F. Sustersio is manager at the mines.—Two railroads that would open up mineral districts in Jalisco and extend from Guadalajara to the Pacific coast are projected. A. W. Geist, formerly of Denver, proposes to interest Colorado and New York capital in the construction of a road from Las Penas, on Banderas bay, as the Pacific terminus. F. M. Ames, an engineer who has charge of some of the Denver & Rio Grande construction work, has made a reconnaissance and is preparing an estimate of the cost of building the line. The other railroad is being promoted by M. C. Miller of Minneapolis, Minn., and the company to undertake its construction has been incorporated under the laws of South Dakota with a capital of \$12,000,000 gold. This road is planned to run via Cocula and Autlan to the port of Chamela. The mountains around Autlan contain some of the greatest copper deposits in Mexico, but the ore is principally low grade.—J. F. Burns and others of the Portland G. M. Co. of Cripple Creek, Colo., are working the Lupita mine, in the Navidad district. The Lupita is a silver-gold property, developed by tunnel on the vein, and the present production is 225 tons daily. The mine is equipped with a steam hoist. The majority of the ore is high grade and the greater part of it is shipped to the smelters. The expense of shipping, smelter charges, etc., amount to \$65 (Mexican) per ton. The lower grade ore is treated in the company's mill on the Mascota river. A cyanide plant, to treat the tailings after concentration, is to be put in.—B. H. Hammett intends to begin work on placer ground in the Pihuamo district.—D. P. Richardson of St. Louis, Mo., and J. Dee of Cocoma, Jalisco, have organized the Cocoma M. & S. Co., to operate the Blake mines, 65 miles west of Ameca.—R. C. P. Smith and associates of Los Angeles, Cal., have bought the Refugio mine, between Ezatlan and Anahuac, from W. M. Mathews, and have commenced development work.

Coahuila.

The Constancia M. Co., composed of Saltillo people, is shipping 4000 tons of ore from its properties in Sierra Mojada. It is operating two of its ten mines and has several properties leased to other concerns. W. Hagemann is general manager.

Tepic.

The Zapopan G. M. Co. proposes to build a cyanide plant at its mines in La Yesca. C. C. Bruckner is manager.

Chihuahua.

A discovery of hismith by T. J. Driscoll is reported from near Ojo Caliente.—C. C. Chase, manager of the Greene Gold-Silver Co., says that W. C. Greene has bought the Santa Brigida mine and mill from Greer & Lanchan and that work would be started thereon. The mine is a silver-gold property which has been worked considerably, but the former owners had put in a mill poorly adapted to the treatment of the ores, and had not the means to go on with the operations. The mine is on the Greene lands in the Sierra Madres, near the Cerro Boluda mine.—B. Gilpin of Cripple Creek, Colo., has taken a lease and bond on the Prieto mine at Parral. He intends pumping the water out and sinking the shaft deeper.

Zacatecas.

The Mesquite Gold Mines, Ltd., at Mesquite del Oro intend to enlarge their cyanide plant. Maurice Cockerell is manager at the mines.—It is reported that B. C. Wheeler is building a cyanide plant to treat ores from the La Novia mine, in northern Zacatecas.

Personal.

H. C. RENO is superintendent Trinity M. Co., Magdalena, Ariz.

F. J. BOOTH is superintendent Kings M. Co., near Cholame, Cal.

H. T. MCALISTER is superintendent Mary Verna mine at Frisco, Colo.

W. K. FRAZER, of Deadwood, S. D., is examining mines in Mexico.

T. F. HOPKINS is manager Golden Eagle M. Co., Grants Pass, Oregon.

W. A. THOMPSON is superintendent Gold Cliff mine, near Weatherly, Or.

G. F. COLTON is manager Duplex mine, Searchlight, Lincoln county, Nev.

C. S. NEWSOM is superintendent Washington-Joliet mine, Breckenridge, Colo.

S. JAMES is superintendent smelter of Las Aztecas M. & S. Co. at Arcos, Mexico.

J. D. SPARGO has resigned as superintendent Gold Road M. & E. Co., Acme, Ariz.

A. Z. CONRAD, secretary Columbus Con. M. Co., of Deadwood, S. D., is in London.

M. M. HOWE is manager Senator mine on North Star mountain, near Breckenridge, Colo.

A. B. MYNOTT has charge of the cyanide plant at the San Alhino mine, El Jicarra, Nicaragua.

F. H. LESCHEN, of Los Angeles, Cal., has opened an assay office at Silver City, New Mexico.

A. A. HEAD of Denver, Colo., has charge of the new mill at Silver Cliff, Custer county, Colo.

J. G. ALLYN, of Chicago, Ill., has been examining properties at Cienegardo Olivas, Mexico.

G. H. CARNAHAN is manager Cia Metalurgica Mexicana, operating Veta Rica mines at Sierra Mojada, Coahuila, Mexico.

C. H. MCMAHON has resigned as superintendent Moeztuma Lead Co., Chihuahua, Mexico, and will give his time to private practice.

C. E. WILBUR, manager Standard Nitrate Co., is at the company's nitre properties in the Chimehucuis valley, 30 miles south of Needles, Cal.

H. T. MCALISTER is superintendent Mary Verna mine at Frisco and of the North American Mines Co. at Uruva, Summit county, Colorado.

S. E. BRETHERTON has returned to Val Verde, Ariz., where he was sent by Prescott parties to examine and report on copper mining properties.

W. B. ROUNTREE, formerly chief chemist for the Mountain Copper Co., is now smelter superintendent for the company at their Keswick plant.

J. F. MORRIS is in charge of a prospecting expedition on the Erythraean border of the Sudan, and expects to return to London towards the end of May.

W. S. KEYES, E. M., has returned to San Francisco, Cal., from his mines near Panuco, Sinaloa, Mex. He expects to return to Mexico in a few weeks.

REFUS BUCK, C. E., left San Francisco, Cal., on the 10th inst., for Dawson, Yukon Territory, where he will put in a water system for the Klondike mining district.

G. W. MYERS has returned to San Francisco, Cal., from an Eastern trip and goes to Alaska at the end of May, thence to the Oeur d'Alenes and eastern Oregon, thence to Australia and New Zealand.

C. M. EYE, who has been with the Nevada Con. Copper Co. of San Francisco, Cal., for some weeks past, sails May 12th for Manila to erect and operate a cyanide plant near that port. This is believed to be the pioneer installation in this line of milling to be made in the islands. The plant is being sent out to M. A. Clarke of Manila by the Joshua Hendy Machine Works.

Commercial Paragraphs.

THE Western Iron Works, of 908-926 North Main street, Los Angeles, Cal., have changed their name to the Western Gas Engine Co.

THE large plant of the Springfield Boiler & Mfg. Co., Springfield, Ill., was entirely destroyed by fire, May 1st. The loss is covered by insurance and the company will no doubt immediately rebuild.

THE Vulcan Iron Works Co. of Toledo, O., have shipped three more "Little Giant" shovels to South Africa. The Vulcan Co. has shipped a number of this type of shovel into the diamond fields in the Kimberly district.

THE Stanley Electric Manufacturing Co. and the General Incandescent Arc Light Co. have consolidated as the Stanley-G. I. Electric Manufacturing Co., with W. M. Crane as president, C. C. Chesney 1st vice-president, M. D. Barr 2nd vice-president and M. J. Insull 3rd vice-president.

W. G. SCHRON, who has been in the employ of the Westinghouse Machine Co. as salesman, recently entered the service of the Allis-Chalmers Co. of Milwaukee, Wis. He will make his headquarters at their Pittsburgh office and devote his attention to the sale of gas engines, steam engines and steam turbines.

THE Abner Doble Co. of San Francisco, Cal., announces that arrangements have been made with the John McDougall Caledonian Iron Works Co., Ltd., of Montreal, Canada, whereby the latter become sole licensees for the manufacture of the Doble system of water wheels in the Dominion of Canada.

A PARTY of prominent engineers and contractors, identified with tunneling enterprises, visited the Glendon, Pa., quarries of the Ingersoll-Sergeant Drill Co. recently and saw a new method of tunnel driving with channelers, of interest on account of its availability for tunneling under the foundations of buildings, no heavy blasting being required.

THE S. H. Supply Co., Denver, Colo., report sales of the Wild mill as follows: Two No. 2 mills to Osson P. Brown, Mexico; one No. 2 mill to Idaho, one No. 1 mill to the Copperopolis Copper Co., Baker City, Oregon, and one No. 1 mill to Arizona. This mill has just been placed on the market after having undergone several months practical tests and has met with a large sale.

THE Westinghouse Electric & Manufacturing Co., through their Denver, Colo., branch, have sold complete electrical equipment for Lander, Wyo., composed of two 75 K. W. engine-type units, alternating current, 2200 volts, 60-cycle, 3-phase; complete electrical installment for Cody, Wyo., consisting of 150 K. W. 60-cycle, 3-phase, 2200-volt alternating current generator, belted to water wheel; also, complete lighting meter and transformer system.

A. P. HEAD, the London, Eng., representative of the Wellman-Seaver-Morgan Co., has completed a tour around the world and has established the following sub-agencies for the Wellman-Seaver-Morgan Co.: At Melbourne, Australian Metal Co., as Australasian agents. The branches of this concern are as follows: New Zealand—Gilbert Machinery Co., Wellington. Queensland—J. Stothert, Brisbane. N. Queensland—J. Coker, Mackay. New South Wales—W. R. Laidley, Sydney. South Australia—J. C. Fraser, Adelaide. West Australia—A. E. Thomas, Coolgardie. Tasmania—L. Tullock, Launceston. In India the following agents, representing

the Presidencies of Bombay, Bengal and Madras, have been appointed: J. Harper, Calcutta; F. Harrison, Bombay; W. H. Oakes, Madras.

## Books Received.

"A Preliminary Report on the Protozoa of the Fresh Waters of Connecticut," by H. W. Conn, is issued by the State Geological and Natural History Survey of Connecticut. The work is very complete on flagellata and infusoria, but less complete on the rarer groups of rhizopoda, heliozoa and suctorina. The figures accompanying the report will be valuable for students.

Under the subject of water supply and irrigation the United States Geological Survey has issued Paper No. 115 on "River Surveys and Profiles Made During 1903," arranged by W. C. Hall and J. C. Hoyt; Paper No. 116, "Water Problem of Santa Barbara, California," by J. B. Lippincott; Paper No. 120, "Bibliographic Review and Index of Papers Relating to Underground Waters, Published by the United States Geological Survey, 1879-1904," by M. L. Fuller, and Paper No. 122, "Relation of the Law to Underground Waters," by D. W. Johnson.

The United States Geological Survey has been conducting a series of investigations in Alaska that have already done much to make the country known and promise to aid future development. Bulletin 250, by G. C. Martin, describes "The Petroleum Fields of the Pacific Coast of Alaska, With an Account of the Bering River Coal Deposits." The Controller Bay petroleum fields are near the mouth of Copper river, and the Cape Yaktag fields are 75 miles farther east. The Cook Inlet fields are 320 miles west of Controller bay, in the middle part of the western shore of Cook inlet, and the Cold Bay field is 160 miles to the southwest, on the southern coast of the Alaska peninsula. The Bering River coal fields are from 20 to 40 miles from the coast, in the valley of Bering river, which flows into Controller bay. The author discusses the geography, geology and economic materials of each field, and also gives analyses of different Alaska petroleum. Bulletin 259 is a "Report on Progress of Investigations of Mineral Resources of Alaska in 1904," by A. H. Brooks and others, and includes "An Account of Placer Mining in Alaska in 1904," by A. H. Brooks; "Methods and Costs of Gravel and Placer Mining in Alaska," by C. W. Purington; "Economic Developments in Southeastern Alaska," by F. E. & C. W. Wright; "Treadwell Ore Deposits, Douglas Island," by A. C. Spencer; "Cape Yaktag Placers," by G. C. Martin; "Gold Placers of Turnagain Arm, Cook Inlet," by F. H. Moffit; "Gold Deposits of Shumagin Island," by G. C. Martin; "Gold Mining on Unalaska Island," by A. J. Collier; "Rampart Placer Region," by L. M. Prindle and F. M. Hess; "Development of Alaska Tin Deposits," by A. J. Collier; "Coal Resources of Southwestern Alaska," by R. W. Stone, and "Coal Fields of Cape Lisburne Region," by A. J. Collier.

Within the past few years a large number of books have been written detailing methods of chemical analysis. A few are now recognized as standard, and the first question suggested by the appearance of a "Manual of Chemical Analysis" by Eugene Prost, translated from the German by J. C. Smith, is why this latest treatise should take a place among those already in the analyst's library. The answer is found in its conciseness and in its authoritativeness. It presents a selection of methods for analyzing the chief mineral products which the metallurgical chemist is likely to meet in his practice. Its worth is due to the discrimination with which the selection has been made, for the author describes only such processes as have proven satisfactory in a large number of cases. This saves much confusion and possibility of error on the part of the chemist. The subject has been clarified, as it were, by filtration through the tests of experience. The subject range includes fuels, waters, ores, metals, alloys and salts, both native and manufactured, and is preceded by excellent directions for preparing the material for analysis. The treatment exhibits a lucid brevity, facilitating rapid use. For example, in the chapter on copper compounds the author divides them into two groups. The first includes native copper and its oxides, and the second ores containing sulphur, the latter being of far greater importance, industrially. Then follow typical tables of composition of each of the ores. This is an important part of the treatment of each subject, and is of the greatest value to the analyst in directing his course of operations. The object of the analysis is clearly stated and the details of manipulation are presented fully, yet tersely. One is inclined to criticize the limited variety of tests, but is reconciled by the excellence of those presented and by the fact that to do complete justice to each element would require an encyclopedia. The space devoted to manganese is rather brief, magnesium compounds are slighted, but on the whole the book is very good and will prove a valuable addition to the practical man's working library. It is published by D. Van Nostrand & Co., 23 Murray street, New York City, for \$4.50, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Trade Treatises.

"Clutchology," of the Automatic Clutch Co. of Akron, Ohio, describes a clutch for power transmission that grips automatically with the load and cannot slip.

The Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City, issue an interesting pamphlet, form 346, describing "The Central Air Plant," as exemplified in the compressed air power system of the Cleveland Stone Co., North Amherst, Ohio.

## Latest Market Reports.

SAN FRANCISCO, May 12, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 57½c, refined (1000 fine); San Francisco, 57½c; Mexican dollars, 46c, San Francisco; 44½c, New York.

COPPER.—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15@15.25; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £65 18s 9d spot per ton.

Copper continues quiet with no material change in price. All reports indicate a good demand with steady production. That the pending lawsuits against the several smelters of the West will have a noticeable influence on the copper output or the market is doubtful.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 16s 3d long ton.

SPELT.—New York, \$5.65; St. Louis, \$5.70; London, £23 10s per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.90@30.10; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 35@37½c. London, £136 12s 6d.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$33.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, 3½c; 50c; dust, 3½c, 10c; sulphate, 3½c, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c. ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs.: 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 3½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl. CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILES.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

### LUMBER.—(Retail)

Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00@shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2\*, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@2¾c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c per lb.; nitric acid, carboys, 80% B.

OILS.—Linseed, boiled, bbl., 60c; cs., 65c; raw, bbl., 58c; cs., 63c; Lucol oil, boiled, hhl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As; tral, 19c; Star, 19c; Extra Star, 22c; Ecocene, 21c. Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 25½c; Deodorized Stove Gasoline, bulk, 16c,

do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, 2.75 per lb.

CHROMIUM.—90% and over, 3½c per lb., 80c.

PHOSPHORUS.—American, 3½c per lb., 70c.

SODIUM.—Metal, 50c.

BISMUTH.—Subnitrate, 3½c per lb., \$2.10.

URANIUM.—Oxide, 3½c per lb., \$3.50.

MERCURY.—Bichloride, 3½c per lb., 77c.

TUNGSTEN.—Best, 3½c per lb., \$1.25.

SILVER.—Chloride, 3½c per lb., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 3½c per lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, 3½c per lb., 2¼@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, 1 ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MAY 2, 1905.

788,620.—REAMER—J. C. Adkins, Stockton, Cal.  
788,626.—SWITCH—C. A. Bisher, Seattle, Wash.  
788,512.—SULPHUR BURNER—H. Blumhardt Jr., Daggett, Cal.  
788,998.—PENCIL—A. E. Buckingham, Oakland, Cal.  
788,703.—CIGARETTE PAPER HOLDER—Minnie P. Casterline, San Francisco.  
788,886.—ILLUSION—W. J. Citron, San Francisco.  
789,005.—SAW GUIDE—Conkey & Bradley, Chloride, Ariz.  
788,890.—WATER HEATER—P. A. Deasy, Oakland, Cal.  
788,718.—POINT COUNTER—C. Z. Ellis, Berkeley, Cal.  
788,528.—SAW HANDLE—J. Fri, Goshute, Or.  
788,582.—HEATER—Fairchild & Pierson, San Francisco.  
788,766.—BORING MACHINE—F. W. French, San Francisco.  
788,641.—CONTROLLER—B. H. Green, Los Angeles, Cal.  
788,907.—SAWMILL—E. Hoops, Tacoma, Wash.  
788,908.—GUN SIGHT—F. D. Hopkins, San Francisco.  
788,720.—OIL BURNER—Johnson & Noyes, Los Angeles, Cal.  
788,926.—FIBER GRINDER—H. B. Jones, Healdsburg, Wash.  
788,649.—DRAPEY CLAMP—Mary E. Kniveton, Phoenix, Ariz.  
789,038.—MANIFOLD BOOK—A. Levison, San Francisco.  
789,018.—STOCK GUARD—H. A. Middaugh, Seattle, Wash.  
788,580.—SMELTER—G. Mitchell, Los Angeles, Cal.  
788,939.—STUFFING BOX—H. L. Noxon, Bakersfield, Cal.  
788,546.—SLACK ADJUSTER—J. R. Reed, Tacoma, Wash.  
788,674.—BUCKET CLIP—B. C. Rihlet, Spokane, Wash.  
788,729.—STAMP MILL—G. C. Richards, Oakland, Cal.  
788,731.—SLAT HOLDER—G. Schwinn, Huron, Cal.  
788,678.—DOUGH RAISER—J. G. Simpson, Los Angeles, Cal.  
788,856.—CLOTHING TABLE—C. J. Stafford, Bakersfield, Cal.  
789,075.—ENVELOPE FASTENER—M. Terletzky, Goshute, Or.  
788,564.—NAIL SET—T. F. Thompson, Empire, Or.  
788,803.—SANTARY DRAINAGE—F. Walker, Los Angeles, Cal.  
788,804.—EVAPORATOR—J. H. Wallace, San Francisco.  
788,618.—FRUIT GRADER—E. M. Widney, Fernando, Cal.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DUMPING CAR.—No. 788,066. April 25, 1905. Andrew W. Dahner, Sonora, Cal. This invention relates to an improvement in that class of car which is pivoted and tiltable and is provided with a swinging door through which the contents may be discharged. It consists in a means for mechanically opening, closing and locking device for the doors of dumping cars, said device consisting of a lever fulcrumed to the side of the car so as to provide a long and short arm, a curved link having one end connected with the short arm of the fulcrumed lever, and the other with a point stationary with relation to the car, and a second curved link having one end connected with the hinged swinging door and the other with the long arm of the fulcrumed lever.

CIGARETTE PAPER HOLDER.—No. 788,703. May 2, 1905. Minnie C. Casterline, San Francisco, Cal. This invention relates to an improvement in paper holders, and particularly in containers for cigarette papers. The object is to provide a simple, unique and serviceable holder or box which may be carried in the vest pocket and from which successive papers may be removed singly and easily without disturbing the remaining papers in the box. The device consists of a box, a cover hinged to the box having a slot extending transversely across it adjacent to one end, said slot having a length about equal to the width of the box between inside walls, and the width of the contained sheets, and having a lower straight edge and being enlarged and elongated along the opposite edge in the direction of the length of the cover, and a spring-pressed follower in the box co-operating with the cover adjacent to the straight edge of the slot to hold the paper longitudinally of the cover and in the direction of said straight edge.

POINT COUNTER.—No. 788,713. May 2, 1905. Charles Z. Ellis, Berkeley, Cal. This invention relates to an improved playing card holder and game and point counter. The object is to provide a simple, light, artistic, unique and handy metal holder or case which will take up no more room than the ordinary pasteboard case does in which a pack of cards usually comes, but which will have means for recording and counting points and games and will protect the cards when not in use. The device comprises a holder made in two parts, preferably stamped from sheet metal, each having corresponding side and end projections at substantially right angles to the surface of the plate and said side and end projections including a slotted portion on one plate and a tang portion on the other plate and adapted to enter the slotted portion and interlock therewith, said projections affording a support for the edges of the contained pack, the projections at one end being hinged together to permit the plates being opened into the same plane or folded into substantially parallel planes.

STAMP MILL.—No. 788,729. May 2, 1905. George C. Richards, Oakland, Cal. This invention relates to an improvement in stamp mills, and particularly in mills having mortars of the sectional type. In the usual construction of mortars for stamp mills the mortars are cast in a single piece, which is necessarily heavy, bulky and difficult to transport. On the other hand, where it has been attempted to construct mortars of the sectional type there has been difficulty, first, of getting a sufficiently rigid structure, and second, of securing suitably tight joints, both of these considerations being of the utmost importance in a practical mill. Its object is to provide a practical sectional mortar of simple construction, the sections being cast in one piece, easily handled and which may be assembled into a rigid permanent structure having water-tight joints. It consists of three integral separable sections comprising a base with a die recess and a trough surrounding the recess, a central section having radially disposed screen openings and seating on the base between said die recess and trough, an upper section seating on the central section and having a contracted elongated neck to accommodate the stamp and having an integral hopper which discharges into the upper portion of the central section, said sections having interlocking ends whereby they may be assembled and held intact without the use of bolts or other securing means.

## Mining in Mexico.

The difficulties attendant upon mining equipment and operation in some parts of Mexico are well illustrated in the accompanying engravings. These views are in the southern part of the State of Sinaloa, at and near the city of Mazatlan, one of the principal ports of entry on the Pacific side in Mexico. The handling of some classes of freight at this port is illustrated in typical manner where the native laborers are seen carrying goods ashore in baskets, from the lighters, wading hip deep in the water. A second view shows the city of Mazatlan, with its white or buff adobe houses and red tile roofs, which, with the luxuriant vegetation of the gardens and the blue, hazy mountains in the distance, forms a restful and picturesque scene characteristic of this tropical land. Another view is thoroughly characteristic of a type of Mexican life, in the string of ox carts passing through Mazatlan on their way to the mines at Rosario, 45 miles distant to the southeast. Near Rosario is the noted group of mines known as El Tajo. In Spanish a tajo is an open pit or depression in the ground caused by mining operations at the surface, or caves resulting from the collapse of underground workings. The fourth picture is a view of the pan mill at the El Tajo mines. Originally the ores at this mine were worked by the patio process, common throughout Mexico for several centuries past, and still in use to a great extent. The patio, however, is giving place to modern methods and American machinery. There is, however, an interesting phase of this branch of metallurgy which may be called intermediate between the old and familiar patio process and the Washoe process, as practiced in American pan mills of modern construction, and this is the introduction of mechanical means in the patio to replace mules and horses in mixing the charge after it is spread in the patio.

## Damages From Coal Culm.

A great deal has been said in recent years of the damages done by the tailings from hydraulic mines, stamp mills and dredgers, which have flooded low farming lands, but the gold miners of the West are not the only ones who meet with complaints of this nature. In Pennsylvania many millions of tons of fine coal has been discharged from the breakers into the Susquehanna river, and this fine dust-like coal has flooded the low lands along that stream, ruining the gardens and small farms adjacent to the river—and the coal companies had to pay thousands of dollars in damages in past years to the owners of the damaged lands. A million dollars' worth of this fine coal has been recovered by dredging. Fleets of boats are in operation on this river dredging for this coal between Wilkesbarre and Harrisburg. The coal companies argue that, as they have been obliged to pay for the damages these coal fines have caused, the

coal rightfully belongs to them, and it is said they intend to contest in the courts for the right to the exclusive privilege to recover the fine coal from the river bed and its banks. In the Western States there is no doubt as to how a contention of this kind would be decided, but the laws of the Eastern States differ in many respects from those of the West.

SOME heroic work was recently accomplished in a burning coal mine at Edwardsville, Ill., when the miners concluded that their only salvation lay in

cutting out the burning coal. This they did, sending the burning fuel to the surface in the mine cars. The mine workings were filled with gas, and the heat was almost unbearable, but the entire village depended for its existence on the operation of this one mine. With them it was a case of self-preservation and they were found equal to the emergency, as they usually are when herculean tasks are to be performed in a mine, whether to save lives of their fellow workers, or the property of their employers when it is in danger.

THE mine owners and operators of Australia are forming an organization for the purpose of giving them a standing in court in the event of later troubles reaching the courts.

SOME of the minerals of value over which the average prospector passes, or sees without giving them attention, are cassiterite (tinstone), magnesite (carbonate of magnesite), gem tourmalines, beryl minerals (spodumene, lepidolite, etc.), chromite from borates (colemanite, etc.), zinc carbonates and oxides, various structural materials and many others. These are passed by either because the prospector does not recognize them or fails to appreciate their value. He is usually in search of some definite mineral—usually gold or copper—and all others are passed by as unworthy of attention. Another reason for this is that the most of these substances require capital to develop and make them available, which is usually not one of the abundant possessions of the prospector, but he knows that if he is fortunate enough to find a rich gold-bearing vein or a copper deposit, either of them will bring him ready money, for both are in demand. As a matter of fact, however, as much net money is often made in mining for some of the other minerals mentioned as for gold or copper. The output of the other minerals in the United States far exceeds that of gold, silver and copper combined, these three metals constituting only about one-fourth of the mineral output of the United States, where the total annual output now exceeds one billion dollars.

## Some Unsolved Problems in Mining.

The science of mining has advanced to such a satisfactory state, as compared with the past, that the mining engineer is sometimes disposed to look upon the result of his labors not only with complacency, but possibly with a feeling that not a great deal more remains to be accomplished in this direction.

Such a contemplation of results, however, is scarcely permissible when there really remains so many unsolved problems. The problem of successfully mining to a depth 50% greater than that already reached is one of the most serious matters which today confronts the mining engineer. He has satisfactorily solved the problems generally incident to mining at and near the surface, but he has not yet gone much, if any, below 5000 feet vertically, and possibly he may not be required to do so, except with diamond drill, and yet it is positively known that veins and beds of ore exist at and below that depth which would be largely profitable if situated within 1000 or 2000 feet of the surface. The problems of very deep mining are largely mechanical, and there is every confidence that we shall yet look upon mining operations successfully carried on at depths of 7000 feet, and probably deeper, with no more concern than we now feel in contemplating similar operations between 3000 and 4000 feet below the surface. The economic features of each situation must determine this.

There is, however, another and a far greater problem, and that is to forecast, even approximately, the size, character and value of a mineral deposit or vein beyond the point of actual exposure. Within the past ten or fifteen years a great deal of attention has been given to the genesis of ore deposits, and extensive volumes have been written on the subject by careful observers. As a result, to the knowledge of ore deposits of every character has been added a large fund of very valuable information, and yet we are now no better able to "see beyond the point of the pick," apparently, than when the subject was, comparatively speaking, in its infancy.

One of the most remarkable contributions to mining geology was that of Baron Von Richthofen, in his famous little monograph on the Comstock lode, written in 1866, and issued by the Sutro Tunnel Company. This eminent scientist possessed the faculty of "seeing into the ground" to as great an extent, at least, as any of his successors, who have had the advantage of the more extensive development of the great lode, as well as the improved facilities for carrying on such investigations. The theories expressed in this valuable treatise of Baron Von Richthofen were borne out by subsequent developments in a remarkable manner, when all else is considered. As a matter of course, faults and dykes, if unknown, cannot be anticipated, and it is not without some repudiation that a conscientious mining geologist will undertake to forecast the future of an ore deposit or vein very far beyond the exposed faces, though those having a less knowledge of the science of geology and the vagaries of ore deposits essay this responsibility with the utmost confidence.

Some very deep mines furnish in their development some startling geological facts, which tend rather to a suspension of judgment than to a confident expression of what further and deeper exploration may bring forth. There are veins which show successively at different depths a varying type of structure, size and mineral contents, which cause the mining geologist to hesitate in giving an opinion as to what may be expected below. It is as unsafe to condemn a mine which has been a good producer as it is to predict that a poor one will become largely profitable if only greater depth be reached.

Still another problem, and one which the mining engineer views with some concern, is the possible relation of topography to ore deposition. There are numerous places where veins outcrop along the surface near a mountain top and these outcrops are found to be more or less continuous along the surface, down the mountain side to the bottom of a neighboring canyon. These deposits or veins are worked to the depth of 100 to 300 feet along the outcrop, and when the individual ore shoots are exhausted little or no effort has been made to search for other deposits, either by sinking or driving farther into the mountain on the strike of the ore deposits. This is particularly noticeable where the ore bodies occur as a

series of lenses in mica schist and where there is no distinctly marked fissure. If the mining engineer believes the lenses do not go down to greater depth than the bottom of the first shoots opened from the surface, he must conceive that they do bear some direct relation to the surface topography which suggests a very recent formation of ore bodies. The natural impulse is contrary to this theory, and yet we have in mind a number of instances where the mine operators are seemingly slow to put it to the test by actual experiment.

Mining geologists are, however, beginning to lean toward the theory that generally ore deposits and veins, and more particularly the latter, may become larger with depth, but that the values are lower and disseminated through a greater rock mass, though there appears to be no direct ratio between values and size of the vein. It cannot be assumed because a vein at 1000 feet depth and 10 feet in width carries \$10 per ton, that at 2000 feet, where it is 40 feet wide, it will contain only one-fourth the value per ton found where it was 10 feet wide. Although exhaustive study has been given the genesis of ore deposits, there still remains much to be learned concerning these phenomena.

## State Geological Surveys.

There are few if any States in the Union in which there are neither mines nor quarries. Every State has undeveloped mineral resources, but in some instances these lie untouched and in many cases unknown. The geological surveys and mining bureaus of the several States have done much to call the attention of the public to the undeveloped resources and, in view of the great good accomplished by research of this character, it should be a sufficient stimulus to perpetuate organizations of this kind and, by liberal appropriations, to extend their scope and usefulness. The untechnical and inexperienced observer may pass daily over a deposit of valuable mineral and, being ignorant of its usefulness and value, gives it little or no attention. The careful and painstaking investigation of the trained staff assistants of institutions of this character has brought to the public notice many valuable deposits of mineral in numerous States, and it is superfluous to say that work of this description has repaid to the States many times over all the expense which has attached to the maintenance of the surveys. The United States Geological Survey has also done a great work in this direction, and the scope of its investigations is being constantly widened. Under the present administration the work is being more vigorously prosecuted than in the earlier years, and the public are given the desired information much more promptly than formerly. In this early publicity lies much of the value of a geological survey. After mines and districts have been worked out, these sections have little other than a historical interest. What the public want to know is something of the future probabilities, as well as the past and present operations, and the conditions under which these operations were carried on and the results obtained.

AN interesting phase of the metallurgy of copper is the alacrity with which the management of large plants will tear out an expensive installation to replace it with one of more modern design and which it is believed will effect a slight reduction in the cost of producing copper. There is competition in the mining and reduction of base metals, and the concern which can produce and market copper, lead, zinc, tin, iron or some other metal or mineral substance at the lowest cost per unit is making the most money. This condition does not extend into the gold mining industry. In that branch there is no competition in the market, for the product finds a ready buyer at a fixed price. The only competition with which gold mining has to contend is the cost of production, and the man who can produce an ounce of gold for the least cost under stated conditions is considered the best manager.

THE new eight-hour labor law is to go into effect in Colorado July 1st. The Colorado Fuel & Iron Co. it is said, intend to comply with the law, as it will not affect them materially. The miners work by the ton or the yard, and it remains with them to do all the work possible within the working hours.

## CONCENTRATES.

It is never safe to turn water into a steam boiler when no water can be seen in the glass gauge.

THERE are now nearly 30,000 Chinese coolies at work in the mines of the Rand, South Africa. They are said to be increasing in efficiency.

THE body of the Bonker Hill & Sullivan mine, in the Coeur d'Alene district, Idaho, is from 40 to 100 feet in width. It is mostly concentrating ore.

THE Broken Hill Proprietary Co. is Broken Hill, N. S. W., now produces from 1200 to 1500 tons of zinc concentrates weekly by means of the salt cake process.

LATENT HEAT is the amount of heat which must be transferred or communicated to a substance in a given state or change to another state without raising its temperature.

SEMENTITE has a very low melting point—240° C.—and softens at 250° C., but it melts at a lower temperature than either of them, the point of fusion being 200° C.

Oil was known to exist in the vicinity of Los Angeles for many years before any wells were sunk there. On the San Joaquin, not far from the city, oil seepages were noticed in the early settlement of the country.

THERE was a stampede in the North Park region, near Hahn's peak, Colo., about twenty years ago, in search of lead carbonate, samples of which had been found by prospectors, but no ledge were discovered.

By a normal solution volume  $\frac{N}{V}$  means a solution which contains in one liter of water the equivalent of one gram of hydrogen. Thus a normal solution of sulphuric acid contains 98.08 grams  $H_2SO_4$  in 1 liter of water.

MALAYSIAN IRON ORES, although used in the manufacture of pig iron, form only a relatively small portion of the iron output of the United States. Sementite and hematite are mostly used for the purpose of making pig iron.

THE United States produces 77% of the world's coal, 39% of its pig iron, 14% of its copper, 15% of its zinc and 71% of its petroleum. In the production of coal, pig iron, copper and petroleum the United States leads the world.

THE Guanaco mine of Colorado will be, when completed, the longest tunnel in America and the longest transportation tunnel in the world. In all it will be a little over 10,000 feet, or nearly 4 miles from one end to the other.

CHALVAL is lifted by hydraulic devices in some instances 100 feet vertical from the bedrock in the pit to the frame on the surface. At Steamboogie, Colo., the lift is nearly the height, and in Camp Ruster, New Zealand, it is 100 feet.

GRAND MICHIGANS—that is those having a width of more than 10 inches at the level of discharge—have a lower capacity than the narrow Elzevir-type, but they have a greater amount of gold inside the mortar than the narrow rapid-discharge type.

CHROMIUM also oxide is value, but chrome is a natural red oxide of iron which occurs with other ores of iron. Its color is from orange red to deep red. It has a vitreous luster, is brittle, with a hardness of 4 to 4.5. It contains iron 44.5% and oxygen 55.5%.

In the process of leaching sulphide ores in a solution, the sulphides are oxidized either by the addition of air to the charge in the form of potassium carbonate or by the addition of pieces of zinc or iron, which unite with the sulphur to form sulphide of iron. The latter is the method most commonly practiced.

ALL BORAX contains more or less water of crystallization. Borax glass used in leaching is the borax which has been heated and the water is driven out. If the crude borax is introduced with the charge in a crucible it is likely to cause the charge to boil over thus destroying the accuracy and value of the assay.

In leaching the precipitates from zinc precipitation boxes, it is customary to carefully wash the precipitate through a sieve of 100 mesh after leaching to remove any particles of metallic zinc. The percentage of material passing and remaining in the screen is carefully calculated and the two parts assayed separately.

COPPER may be precipitated from an alkaline solution, a p. copper sulphate in ammonia, by hydrogen sulphide the copper going down as copper sulphide. Gold may be precipitated from alkaline solution, such as gold in cyanide solution, by means of zinc shavings, placed in dust. The reactions are variable.

THE main gauge in mine tracks underground, where there is a capacity of 100 to 1500 pounds are driven by men. A 12 inches surface gauge upon which leather tape are used in the gauges from 10 to 12 inches and sometimes wider, particularly where some motive power such as steam, air or electric motors are in use.

MINERALOGICAL machines are most difficult of transportation owing to the trouble in getting positive reactions. It was owing to the peculiarly unobtrusive construction of the machines of this nature that it was first named machine after Thomas of Great Britain, who was installing face is written in the names.

OPERATIONALLY men who have to handle in their disposal with which they save the time intended are directly in the interests of the mortars; but this practice is pernicious and should never be attempted, as it practically makes the mortar for further legitimate use, the stamps picking wearing impressions in the bottom of the mortar.

A SOLUTION of lead four-silicate value contains in excess of four-silicate and is said to be a suitable and satisfactory electrolyte for refining lead. It is not volatile and is readily handled. The lead other electrolytes, is said to cause the lead to build up in the form of irregular branches, which, extending outward, make short circuits by contact.

THE steam engineer should frequently examine the gauge cocks of his boiler, is in the event of their becoming clogged by deposit of mud or scale or from any other cause a boiler explosion may result as was recently the case in board a steam ship in British Channel, England. Investigation after the explosion proved that it was due to a defective water gauge.

When a vein is displaced by a fault much valuable time and expense may often be saved by using the lead wire in the opposite side of the fault plane or like that has delineated the vein, and the shortest route to the continuation of the ore body is by either drifting, sinking or sinking as the case may require according to the dip of the vein and dip of the fault plane.

It is the aim of the lead smelter to make slag in which there is a constant and definite ratio between the iron, lime and silica which form its constituents, but in copper smelting there is a comparatively wide range in the proportions of these substances permissible. In copper smelting the principal object is to make a fluid slag which will permit the free settling of the particles of metal.

THE reason why some iron presents unvarying copper deposits is due to the fact that, as the oxidation of the original material is being proceeded, copper sulphate was formed and was leached out by surface waters due to rain, the copper being carried away in solution, and the iron being left behind as oxide, together with silica and whatever earthy minerals occurred to be present.

THE fact that minute particles of gold are soluble in solutions of cyanide of potassium has been known for ages. It is thought that unworked compounds were first recovered from the barrels of certain pits, such as the mine at Mount, Georgia, and some other veins, which are known to contain pyrite and in small amount. Potassium ferri-cyanide was discovered by a French chemist, Macquer in 1791.

As to the present to the method of extracting mercury from its ore has been found which is a commercial success. Recently experiments have been made in crushing sulphur ore in rotary furnaces, but the method is still to some extent in the experimental stage. The greater part of the mercury of commerce is being produced in the old style vertical furnaces of brick, fired from the sides and equipped for the particular class of ore it is required to treat that is, coarse medium or fine.

CARBONIZATION is the result of the fusing of zinc and pure silica, present in the electric furnace, and is at present only done in the United States at Niagara Falls. As an alternative it is claimed that one pound of carbonization is equal to three pounds of energy being burned. Carbonization is a most valuable and is a most important material for furnace linings, etc. Under some recent patents the material is not used for this purpose without binder.

PLANTAIN is known to occur in California in Santa Del Norte, Humboldt, Mendocino, Plumas, Sierra and Trinity counties, in New York, near Plattsburgh, in North Carolina, in Florida and Southwestern counties of Idaho, in the Wood River district in Oregon, in Coos, Curry, Josephine and Lane counties. It usually occurs in the form of flattened grains in the heavy water sands. A plantain-bearing ore occurs in the Bonanza mine, Topping in Grand Rapids, Michigan, in the form of sperryite, a plantain fluorapatite.

THE light degree of temperature is what a man may work in a mine is largely determined by the humidity of the atmosphere. If the air be moisture laden he cannot work at temperatures much over 100° F. but if the air be dry a higher temperature than this is tolerable and can

be tolerated by the miner. There are some in some of the big mines of the desert in California where men have worked when the temperature was 125° F. or more, but these men suffered more from the heat than from the work.

SEVENTH STAGE is they are called, have some into the positions in which they are found usually by the three methods. Either the stones are practically in situ, and the surrounding rock having been removed by natural decay and disintegration, leaving the stone in position, or the stone is brought to the surface by pressure and raised to the top of the hill or the water has fallen from some higher position, and some of the stones being to support it in the new position have disintegrated and disappeared, or the rock has been carried to its present position by ice. In some of these conditions are found, and passing some others, some very old stones were many years.

SPERMITE is a light-gray, somewhat siliceous, crystalline, colorless, odorless and tasteless substance. The composition of the mineral is variable. The ore is well as being in other upper silicates, particularly silicates and oxides, results more or less directly from the alteration of spermatite. Combinations of spermatite with lead, iron, arsenic and other minerals with silicates forming distinct ores in which the upper is usually subordinate to the other metals present, are not necessarily included in the above, as they may have been formed from mineral solutions lower and not as the result of the alteration of ores previously deposited.

MAINTAINING MOVEMENTS are caused by pressure movements of the winding cable to the hook. One of the safest methods of attaching the cable to the hook is by forming the end of the rope around a shackle or proper size and securing the ends by means of two or three substantial machine iron clips. The ends of the wires should be wrapped after a liberal supply of rope "tongue" has been applied in plenty, made to cover the loose ends of the rope wires from injuring the inside of the sheaves using the pulleys or ship. In a rope the end of the rope is not within the reach of the men riding upon it and there is no need for its wrapping. Again, every six months this over and if the cable should be not about 1 foot above the sheave and the end again turned back around the shackle. This is a guard against the danger of breaking of the cable due to deterioration. The nine wires in the rope always run to the lower end and the likelihood of twisting and consequent weakening of the wires at that point is thereby greatly increased.

SEVERAL men, who are strong and well defined in figure, besides the surface in the form of numerous strangers, some of which have material value, but which may be considered as indicators of the possibilities being beneath. This peculiar condition is probably due to the fact that the ore in the hanging wall side of the fissure when the movement in the veins took place. The wedge-shaped segment of hanging rock overlying the plane of fracture being that is easily crushed and destroyed and mineral solutions passing along the vein or zone or fracture and may escape in the numerous cracks and veins extending upward to the surface. The discovery of such a vein of mineralization should be followed by certain proceeding, a start should be made in this case of mineral and should the shaft pass out of the mine sinking vertically a prospect should be run to reach it in greater depth. It is generally the better plan to sink the prospect shaft in no mine in the direction of the dip of the small veins, always bearing in mind that the veins probably have a steeper dip than the plane of the main fissure, and in some instances they dip in the reverse direction—that is, upward the first vein. This was the case in some of the smaller discoveries in the Comstock Lode, where it was at first thought, owing to the surface veins, that the veins dipped west. When the first fault vein was encountered it was found to dip east in about 45°.

WIND PUMP is used in pumping material in two of the main mines in Carbon county, Mont. one in Castle Gate and the other in Sunnyside. Wind power is the motive used in the mines. The wind pump is used for pumping material, and the stone is fired by electricity or light when it is not run of the mine. These two mines are very busy, the first is in an extensive mine, and the use of wind pump is an additional precaution against fire explosion, the fire being shut out after there is a heavy run and the wind pump will not raise fire as was first used for pumping is not in use. The wind pump is made in Florida, California, and sometimes the ordinary wind pump used in the manufacture of paper. It is a very heavy ground material, having about the appearance of yellow iron ore. Before being used it is always wet, so that it can be packed and held like snow. After it is wet it is squeezed by the hands so that it has the consistency of ordinary mud, and in this state it is put in the line in any of the powder and tamped in the other pumping material. At the other mines of Mont., near Castle Gate, where most powder is used, mud is not obtained either from the inside or the outside of the mine, is used for pumping. In addition to the above precaution, the prevention of fire explosion, the mines are all supplied with a pipe system for carrying water through them, and the miners and engines are kept thoroughly wet to prevent the drying of dust, as have run shaft.

## The Metallurgy of Copper at Anaconda, Montana.

Written for the MINING AND SCIENTIFIC PRESS by  
A. P. MALLON.

The winning of copper from its ores dates back to primeval times, comprising, in variety, wet methods, as at Rio Tinto, Spain, and the more recent dry processes, as those employed in various parts of the United States, particularly at Anaconda, Montana.

In the extraction of the metal at the latter smelter there are several connecting processes, each of prime importance to the ultimate success of the plant, and which may be said to commence at the Butte mines and terminate at the refinery of the Washoe smelter.

To present the subject in an extensive treatise would require a volume, but it is only the object of this article to outline the rather complicated treatment of an ore as practiced at a modern copper plant, and consequently the ore will be traced in its various changes from the laying down at the concentrator to the shipping of 99.5% copper from the refinery.

As is well known, the ores of Butte are largely low grade and sulphide in character, which necessitates their working on an extensive scale. This is accomplished by the amalgamation of several of the mines in the district. The handling of the enormous daily tonnage is facilitated by the operation of the company's railroad connecting Butte with Anaconda, the crude ore being stored at the concentrator building. On analysis the ore shows the following composition: Silica 58%, iron oxide 16%, sulphur 17%, copper 4%, 1 to 6 ounces in silver and .01 to .02 ounce in gold.

The iron, although not present as the oxide, is calculated as such owing to the fact that the sulphur, with which it is invariably combined, bears the most important part in the smelting of the ore. The latter, therefore, is determined separately. In order to obtain a product from this ore which can be successfully treated in the blast or reverberatory furnaces, it is first crushed by various sized rolls and passed over a series of jigs (both coarse and fine), or concentrated on Wilfley tables. Three products result from the former treatment, namely, coarse concentrates, fine concentrates, and tailings. In the coarse concentrates the silica is reduced to 30%, the iron oxide increased to 28%, the sulphur increased to 29%, and the copper to 8%. Similarly, the fine concentrates have a composition of silica 26%, iron oxide 31%, sulphur 34%, and copper 8%. The tailings are sluiced away and show 90% silica, 3% iron oxide, 3% sulphur, and .8% copper.

Some of the crushed ore is not jigged, but is passed over the Wilfleys, which produce Wilfley concentrates and Wilfley tailings. These concentrates show an increase in copper over the jig product, which is probably due to the sizing before concentration. They have a composition of silica 42%, iron oxide 22%, sulphur 24%, and copper 10%. The tailings have silica 92% silica, 2% iron oxide, 3% sulphur, and .8% copper. There are three products which may now be handled to advantage in the blast and reverberatory furnaces, viz., coarse concentrates, fine (jig) concentrates, and fine (Wilfley) concentrates. Since oxidized ores are more susceptible to treatment in reverberatory furnaces, the fine concentrates are submitted to calcining in McDougal roasters. After treatment the roasted concentrates show a reduction in sulphur of nearly 20%. Calcined concentrates, calcine barrings, and McDougal flue dust result from the operation of roasting. The calcined concentrates have a composition of silica 30%, iron oxide 42%, sulphur 9%, and copper 10%, showing an increase in iron oxide and reduction of the sulphur, the copper remaining the same.

Calcine barrings are lumps of partially fused concentrates which adhere to the rakes in the roasters, and consist of 8% silica, 60% iron oxide, 6% sulphur, 12% copper, and 5% aluminum oxide. This product is utilized in the blast furnace owing to the large percentage of iron, which makes a fluid slag.

In nearly all smelting operations a great loss occurs by volatilization. In the case of roasting this loss is exemplified by the production of a flue dust which contains 36% silica, 27% iron oxide, 19% sulphur, 10% copper, and 5% free sulphuric acid. This valuable product is made into briquettes in combination with raw concentrates and various other flue dusts, and smelted in the blast furnaces.

In the production of a matte in the reverberatory furnaces the following charge is added: Fine concentrates, calcined concentrates, flue dusts, coal and lime. The matte produced is of a higher grade than that resulting from the blast furnace, being of the following composition: Silica 1%, iron oxide 22%, sulphur 24%, copper 47%, aluminum oxide 3%, arsenic and antimony (combined) 2%. The slag is granulated by running direct from the furnaces into flowing water contained in sluice boxes and carried to the dump. It has an analysis of silica 40%, iron oxide 46%, calcium oxide 12%, and copper .2%.

Blast furnaces do not require a finished product for their successful operation, the essential constituent of the charge being a sulphide ore. Pursuant to the above, the first-class or high-grade ores, containing

from 8% to 15% copper, may be added direct. In addition to the above ore, the charge consists of coke (usually 10% on a 5-ton charge), calcine barrings, briquettes, and lime rock (54% calcium carbonate). There are five blast furnaces, having a capacity of 1000 tons daily, but additions are at present being made to this department which will greatly increase the daily tonnage. Blast furnaces produce matte, slag, and flue dust, just as in reverberatory smelting, their compositions being very similar. Blast matte has an analysis of 1.9% silica, 24% iron oxide, 26% sulphur, 44% copper, 4% aluminum oxide, and 1% arsenic and antimony (combined). The slag consists of silica 41%, iron oxide 28%, calcium oxide 22%, copper .2%, and aluminum oxide 8%. The flue dust has an analysis of 36% silica, 22% iron oxide, 10% sulphur, and coke dust in variable amounts. In these analyses the percentage of aluminum, arsenic and antimony is taken into consideration because these minerals are deleterious both in the converting of the matte and also in the commer-

The New Rowe Mill at the Mouth of the Yak Tunnel, Leadville, Colo.

cial value of the finished product. Aluminum in excess makes the matte difficultly fusible in the converting, and arsenic and antimony in quantities over 3% or 4% will render the copper practically useless, commercially. Hence it is desired, as far as possible, to eliminate, by fluxing suitably, these objectionable minerals from the matte.

The next step in the operation is the converting of the matte into metallic copper. For this purpose a cup-shaped vessel capable of holding the product of each furnace is used. The process consists in blowing air through the matte, eliminating the sulphur by forming oxides of that metal. In order to protect the sides of the converter from corrosion, a lining is used made up of a mixture of clay and low-grade quartz ores. The lining is tamped in place several hours before using. The iron, silica, and alumina are slagged off by uniting with the lining. The slag comes to the surface of the charge and can be poured as soon as formed. It consists of 35% silica, 56% iron oxide, 4% aluminum oxide, 4% calcium oxide, and 1.8% zinc. The metallic copper which collects in the bottom of the converter is poured into receptacles, which are of such a shape as to make a suitable anode for use in the refinery. Blister copper is of a slightly lower grade and is sent to the refining furnace, where it is subsequently made into anodes. These products show by analysis 97% copper, traces of arsenic, antimony, iron, sulphur, aluminum, and 80 ounces silver to the ton.

The concluding step consists of the refining of the converted copper. This is accomplished by means of electrolysis, the copper being used as an anode and a solution of 32 grams of copper and 140 grams of sulphuric acid per litre acting as a conductor or electrolyte. The anode dissolves gradually in the electrolyte and deposits on the cathode, which is a thin strip of copper. The action is allowed to proceed for forty days, in which time the anode is completely dissolved. The cathode or electrolytic copper is the finished product of the smelter and is shipped to Perth Amboy, New Jersey, refiners, where it is made into bars, ingots, etc. This product is 99.5% pure, having .0015% arsenic and antimony combined.

The silver contained in the anodes collects in the bottom of the solution tanks as a black mud, which is sold to refiners of smelter products.

We have seen how the copper is extracted by following each step with an analysis of the product, so that in noting the various changes of the elements a practical idea of this fascinating subject can be obtained, even more so than by a visit to a modern copper smelter, where the operations on such a large scale are apt to confuse a novice.

## The Yak Tunnel.

One of the most important mining enterprises of Leadville, Colo., is the Yak tunnel, the portal of which is in California gulch, on the south side of Iron hill. It passes under Iron hill and beneath Breece hill—a distance of over 11,000 feet—passing under a score of mines and into the consolidation known as the Ibox property. The tunnel drains an important section of the Leadville district and also furnishes a convenient and inexpensive means of transportation of the ores mined along its line, as well as supplies good ventilation to the mine workings. The mines along the line of this tunnel produce exclusively sulphide ore, much of which is low grade and requires concentration. Recently there has been built near the mouth of the Yak tunnel a reduction plant known as the Rowe mill. This mill has been built after special designs and it is expected that some experimental work of great value will be accomplished by

it. W. W. Davis, manager of the Yak Tunnel & Mining Co., is also manager of the mill. The accompanying illustration is that of the Rowe mill.

## Mining in Nicaragua.

Consul Bingham, in his official report for 1903-4, says that the gold exported during the year was valued at \$570,000 and was obtained chiefly in the range of mountains that, continuing from Honduras, passes through Nicaragua from north to south. Of this amount, only \$25,000 comes from the west side of the range and the remainder from the east side.

Gold mining has been carried on for many years on the west side of the Cordillera range of mountains, but it is only within the last twenty years that this industry has to any extent been opened up on the east side. Considerable as is the amount of gold now exported from the last-mentioned district, but comparatively few mines as yet have been opened up and are in working order, and it is certain that the whole of the eastern side of the Cordillera is very rich in minerals, and in the course of years will be greatly developed. At present the industry is very much retarded by the scarcity of labor, of water in the dry season, and, more especially, by the entire absence of roads and means of easy communication. Provisions and heavy pieces of machinery have to be carried for many miles up the rivers in open canoes, liable to be capsized in the many rapids that have to be ascended and to danger from rocks and sunken logs. After ascending the rivers, the packages have in many cases to be carried to the mines on men's backs; but few of the companies have been able to make roads from their mines to the river banks passable for ox carts or even pack mules. At first the extraction of gold in this district was to a certain extent retarded by the rebellious nature of some of the ore; but this of late has been more or less overcome by the adoption of modern and scientific methods of working.

In shaft sinking with machine drills the miner must place his holes with reference to the dip and strike of the rock in which he is working, if there is any "rift" to the rock at all. Failing this, the holes may not break nearly as much as was calculated. In massive ground, which breaks more or less indiscriminately in any direction, holes may be put in after a regular system in which the central or "cut holes" form an important factor.

## Precise Lining of Large Shafting.

Written for the MINING AND SCIENTIFIC PRESS by  
W. I. FLECK.

When large shafting is to be set, and the revolution per minute is high, or near the ordinary limit, it is of the greatest importance that centering of boxes

curve leaving the pitch line would equal about  $15^\circ$  and the parting strain equal two tons. The loss by friction would be more than doubled—i. e., the power resolves itself into two forces, one acting on the tangent of the pitch line and the other force acting perpendicular to it, at the point of nearest contact of the pitch lines.

One of the forces represents power and work, the

Diagram Showing Method of Lining Shafting.

be lined under conditions so they will remain in position under the working load. The details are given by describing a particular setting, which illustrates most of the important features of this method, some of which are thought to be original and ideal. The drawing shows the relative position of the horizontal and vertical boxing, shafting, gearing, etc., necessary for the transmission of 1600 H. P. from four water wheels through 60 feet of shafting, 7 inches in diameter, 360 revolutions per minute.

The horizontal bearing only will be considered, as the vertical bearings were lined by means of a vertical plumb bob and line in the ordinary way.

The bushings are phosphor bronze,  $\frac{1}{2}$  inch thick, 2 feet long, turned up true, and are not adjustable.

In each end of every bushing a crosswire frame was placed, and the crosswires centered by means of small dividers to within  $\frac{1}{16}$  inch. This was done after the block was set by moving the pins. As the wire was No. E violin string,  $\frac{1}{16}$  inch in diameter, this was easily done.

The hole in the crosswires block was  $1\frac{1}{2}$  inch in diameter, as shown, leaving room for light and numbering. There being six horizontal bearings and one crosswire for each end, the numbers read from one to twelve, in the order of their distance from the observer.

The final setting was done at once easily by means of a transit, which magnifies 24 diameters, set 7 feet in front of No. 1, which is in position. The problem is to make all conform, having two fixed points. When the focus of the objective is changed to No. 2 the crosswire No. 1 disappears, so there is no confusion to the observer.

The assistant holds a small scale reading to  $\frac{1}{16}$  inch successively in a horizontal and vertical position, parallel and near the wires.

The distance read on the scale between the two horizontal crosswires is marked off on the lower side of the box, if it is low, and on the upper side if high.

When the vertical wires are read the distance is marked on the right or left, and shows which way the box is to be moved. By changing the focus successively from one number to the other, all are marked off.

The boxes are changed approximately to their indicated position, then are checked over until the desired accuracy is obtained. As the transit magnifies 24 diameters and the wires are about  $\frac{1}{16}$  inch in diameter, assuming the objective to be tight, the error of alignment is slight, except for error of focusing, which can be checked by changing the transit to the opposite end. By suspending a plumb line over each vertical box and allowing the bob to swing below, these lines are adjusted by the transit and the vertical bushing adjusted by measuring the upper and lower end on four points with a pair of dividers, centering and placing in a vertical position. This part, however, is an indirect method. The shafting was very rigid and stiff; the bolted couplings were 18 inches in diameter, keyed on and turned up afterwards at the factory. They all went easily into place and were found to be in line after the running load.

Shafting for carrying bevel gears must be very stiff for assuming the teeth to run on the pitch line at the full load, and the average angle of all teeth engaged to be  $5^\circ$ . As the pull on the teeth equals eight tons from the parallelogram of force, the resistance or pressure to spring the shaft is approximately 1500 pounds. If the shaft should spring  $\frac{1}{8}$  inch, the

## Ditch Making in the Klondike.

The most important ditch on Bonanza creek, in the Klondike region, is the Norwood ditch, which was built by H. H. Norwood in the summer of 1904. George T. Coffee was consulting engineer and Rufus Buck civil engineer on this construction. The ditch will carry 1000 miner's inches, having a grade of 8.5 feet to the mile where ditch and flume are used and a grade of 40 feet to the mile for pipes, which are 24 inches in diameter. The ditch is located on the right bank of Bonanza creek, the point of diversion being at Claim No. 53 above discovery. The total length of the system is 6 miles, the water being used principally on the groups of mines on Gauvin hill and Magnet hill, which are owned by H. H. Norwood et al.

One of the accompanying engravings shows the reversible road plow benching off the side hill. This was found to be a very economical machine. The ground being cleared was plowed and then the road plow pushed the loose dirt off the grade. The ditch was then excavated in the "bench" thus prepared.

The second illustration shows the pick-and-shovel men excavating for the ditch.

The use of six horses on the road plow tends to settle the loose dirt on the outside bank, which is very good practice, as the ditch will certainly be stronger with a well packed bank.

The cost of such ditches varies, according to material and slope of hillside, from \$2000 to \$4000 per mile.

Labor received \$4 and board per day (\$2 being cost of board). Teams of two horses, with driver, were bired for \$15 to \$20 per day.

The future success of placer mining in the Klondike region must depend to a great extent upon hydraulic methods of mining. The water carried by this ditch will be used under 100-foot head in hydraulicking the gravels on Bonanza creek. The gravel is friable and easily washed when the frost is out of it, and 1000 inches of water under a 100-foot head will break down as much gravel as the water will carry away. The benches where these mining operations are to be carried on are 300 feet above the creek bed.

Grading Bench for Ditch With Road Scraper in the Klondike.

Cutting a Ditch After the Grade Has Been Made in the Klondike.

## Examination and Valuation of Mines.

In a recent lecture before the mining college at Otago University, New Zealand, Professor James Park of the geological department gave the following advice and information to the students of that institution, as published in the New Zealand Mines Record, and it may be read with benefit by all engaged in the mining industry:

The examination and valuation of a mine or mining property is work intrusted to the experienced mining engineer and not to the mining student. But the experienced mining engineer of twenty years hence is in the classroom to-day; thus it is necessary for the student of to-day to become early acquainted with the first principles of what will form the most important function of his profession.

The payable ore in a vein, or coal in a seam, is manifestly a certain finite quantity; therefore the greatest coal field and largest ore deposit must eventually see a day of exhaustion. And if the total quantity of ore or coal and the annual output are known, the date of exhaustion is a matter of simple calculation.

A mining property blessed with a good constitution—that is, endowed with a considerable quantity of valuable ore, from the date of discovery to the point of exhaustion—naturally passes through the successive stages of infancy, youth, full-grown manhood, middle age, old age and extinction.

Infancy is the discovery stage of mine existence; youth, the development stage; full grown, the payable going concern in the meridian of life; middle age, the going concern past the meridian; old age, the period of rapid decadence and exhaustion. But all this is true only of the mine that survives the early stages of existence and lives what may be termed a full and profitable life, leaving an honored name behind.

Some mines give promise of their later vigor even in early infancy, and others that are weakly in infancy develop into the most robust manhood. The greatest mortality takes place in infancy and youth. Scores of promising mineral discoveries are unable to survive the stage of development. They never become going concerns.

But sudden exhaustion is not an affection peculiar to the very old or the very young mine. There are many notable examples of vigorous mines coming to a sudden end through exhaustion of the ore reserves in a way not expected or provided for by the management.

The mine examiner will, therefore, like the careful physician, have an eye open for possible constitutional defects that may cause sudden decadence in even the most vigorous. A mining property may be examined by a mining engineer for the following objects: (a.) The purchase of mine by his principals. (b.) The purchase of shares or a share interest. (c.) Recommendations as to future development work.

The examination and valuation of a mine go hand and hand, but mine examination is a very different thing from mine valuation. Two independent engineers may examine the same property and collect the same data and information, but form quite different conclusions as to the prospective value of the property.

Experience and the personal equation count for much. The latter means that some naturally possess a sounder judgment and more discriminating mind than others; are better able to comprehend the meaning of facts, and hence more competent to form a true conception of a proposition presented to them.

The valuation of a mine is a prosaic, matter-of-fact problem requiring the exercise of the commercial faculty. Even in the most favorable circumstances the problem is not easy of solution, for the reason that some of the essential factors are often wanting, or merely represented by approximations.

For the purposes of examination, mining properties may be considered as belonging to one of three classes, as follows: (1) Metal mines; (2) coal mines; (3) alluvial mines.

**VALUATION OF METAL MINES.**—In the case of a property known to be metalliferous, or to contain some valuable mineral, the scope, and to some extent the method, of examination will be modified by the stage the mine has reached in its existence. The different stages in the life of a mine may be subdivided as follows: (1) Discovery stage; (2) development stage; (3) going concern stage; (4) decadent stage; (5) abandoned.

**DISCOVERY STAGE.**—In this stage we assume—(a) That a vein or ledge has been located by the prospector and a legal title obtained for the ground, forming what may be termed a surface show; or (b) that the claim has been pegged out on position alone, no vein or seam of valuable mineral being exposed at the surface.

**A SURFACE SHOW.**—In this case the outcrop has probably been prospected by trenches and shallow shafts sufficient to disclose the width, direction of the strike and dip of the deposit.

Having provided himself with the best topographical and geological maps obtainable, the mine examiner will proceed with his examination, which will

embrace a consideration of the following points: (a.) The geological features. (b.) The physical features, particularly with reference to the subsequent working of the property, should the results warrant this course; note such points as the backs available—that is, if the vein can be worked water free; but, if not, mention if sinking is likely to be wet or dry; mine timber and water power available, etc. (c.) Sample the outcrop at different points, noting the width of vein and peculiarities of structure. (d.) Mention the proximity, or absence, of valuable or worthless mines in the district. (e.) Make inquiries as to past history of the field, obtaining official statistics when possible. (f.) Gain a personal knowledge of the local peculiarities of the ore deposits in the neighboring mines, especially noting vein structure, average width and value of ore, accessory minerals, country rock, influence of different kinds of country, faults, intrusive dikes, methods of treatment, monthly output, mining costs, etc.

When once on the ground, the mine examiner should make a point of acquiring all the general and particular information he can obtain for his future reference and guidance.

The results of the sampling and observations may be satisfactory, but the experienced mine engineer will be careful not to commit himself to a definite opinion as to the potential value of the property upon surface indications alone. The young engineer must not be afraid to report to his principals "that the development work is insufficient to enable me to form a definite opinion as to the probable value of the property." The experienced engineer finds no difficulty in doing so.

If the outcrop values and general surroundings are satisfactory, the examiner will, in most cases, be warranted in recommending further development work being undertaken in order to open up the ground for a fuller examination. The mine examiner, from his knowledge of the ground, will be able to indicate to his principals the nature, extent and probable cost of such work.

In this case it will manifestly be to the interest of the intending purchasers to acquire a working option over the property for a period of six, nine or twelve months, or, may be, if the work to be undertaken is considerable, two years.

The deed of option should be legally executed between the interested parties; clearly specify the terms of purchase, and state which party is under obligation to pay rents, taxes, royalty and comply with the labor regulations, etc., during the currency of the option.

The vendor may sometimes acquire an immediate cash payment of an agreed sum of money on the execution of the deed of option, such sum to be considered part of the purchase money should the property be taken over; or he may covenant that a certain specified sum be spent in mine development, either monthly or during the whole period of the option, as a guarantee that the work will be prosecuted with vigor.

It should be remembered, however, that the engineer for the purchaser is generally the best judge as to what sum should be spent in the development work necessary to enable him to form a reliable opinion of the value of the property. On the other hand, the chance of doing good business should not be lost by pursuing a niggardly policy with the vendors. Therefore, each case must be judged on its own merits.

So far we have assumed that the surface outcrops gave sufficient values to warrant further development being taken, with a view of opening up the ground for a more critical examination. According to the configuration of the surface and position of the outcrops, the ore vein will be prospected by levels driven "end-on," i. e., along the course of the ore body; or by crosscuts and levels therefrom; or by a shaft or shafts.

In selecting the sites for the aforesaid level or shafts it is in most cases advisable to keep in mind the possibility of these works being utilized in the permanent working of the mine, should the results justify this course.

Again, the surface outcrops may be worthless and the prospects insufficient to warrant any expenditure on prospecting. On the other hand, the value of the property may be so obvious that the mine examiner is justified in recommending the immediate purchase. In this case no prospecting should be undertaken by the examiner until a firm option of purchase has been acquired on bedrock terms.

Undeveloped properties of such obvious value are rare, and hence extreme caution must be exercised by the examiner before recommending an immediate purchase. Ledges of silver-lead ore and gossans of pyritic ore bodies have been discovered in situations that left little room for doubt as to their great value, even from surface sampling and examination; and the same has proved true of not a few valuable deposits of magnetite, specular iron and manganese.

But even if the examiner have the immediate purchase of the property in his mind, he will seldom have much difficulty in obtaining the right (under an option of purchase) to spend a month or two in sampling and surveying preparatory to the completion of the purchase.

**STAKED ON POSITION.**—This is generally an undeveloped property, often possessing no surface indica-

tions of valuable ore or mineral. In some cases position means everything; in others it means nothing. For example, an area surrounded by working coal mines, iron mines, or oil wells occurring in the same formation, in the absence of faults or igneous dikes, is an area already proved valuable by its juxtaposition to valuable mines. Or a claim pegged out on the strike of a lode that has proved to be payable up to the boundary is a potentially valuable property. Or a claim pegged out on the dip of a flat-lying lode, seam, or bed that has proved to be valuable by the outcrop mines is a property, in the absence of great faults, igneous dikes, or a change of rock formation, that may prove to be of great value.

In the above figure, A is an outcrop claim assumed to be valuable. Here B and C are claims pegged on position, and their potential value will depend upon the value and characteristics of the ore body as disclosed by the mine working in the outcrop claim.\*

Manifestly the value of claims B and C can only be determined by shafts or by bore holes. In the majority of cases boring will be resorted to as being cheaper, quicker, and affording the means of testing the deposit at a greater number of points.

Claim D has been pegged out on position. It is next to the outcrop claim, but being situated on the footwall side of the deposit its position counts for nothing.

In the case of steep lodes, claims pegged out on the dip side may be worth little commercially, from the extreme depth at which mining operations would have to be conducted.

In this example claim B may be for all practical purposes of no more value than claim C.

The valuation of position properties presents many difficulties. The mine examiner will therefore need to make a critical examination of the ore bodies in the adjoining mines, of the geological structure of the country, and a particular search for any change of country, dikes, or faults.

The points which the examiner will bring under the notice of his principals are as follows: (1) Situation of claim and means of access; (2) area of claim and name of owners; (3) title—i. e., leasehold or freehold—with particulars of rents, royalties, labor conditions, etc.; (4) geological features; (5) physical features, mentioning climate, forests, water power, etc.; (6) particulars of vein outcrops, prospecting work done; (7) values obtained from sampling; (8) discussion of general surroundings; (9) opinion as to future prospects, and recommendations.

Three courses may be pursued, according to the circumstances—i. e., the property may be—(a) Rejected; (b) secured on working option; (c) purchased.

If the engineer recommends that an option be secured, he should give full details of the character and extent of the proposed work, its probable cost, time required for the work, its effect when completed, and proposed method of supervision.

**DEVELOPED MINES AND GOING CONCERNS.**—The commercial valuation of a mining property in this stage is based upon the following considerations: (a) The quantity and value of ore in sight; (b) the net profit per ton; (c) the annual output to yield a net profit per cent on a certain capitalization; (d) the probable life of mine.

The quantity of ore that might be expected to be opened up by further development work must not be lost sight of. But the quantity and value of such ore are unknown quantities, and the importance to be attached to them in calculating the mine value must in every case be determined by the character of the ore body and the value of the ore already developed and won.

Some veins are notoriously patchy, while others are equally consistent as metal producers; hence no safe rule can be laid down as to the prospective value of undeveloped ground. The local conditions must

\*There are no extralateral rights in New Zealand.

govern each case. It is, however, well for the engineer to remember that the ore values of vein deposits are more liable to sudden variation than those of bedded deposits.

As in the former cases, the mine examiner will proceed to the ground equipped with the best topographical and geological maps obtainable; also official reports and statistics, if any are available.

The examiner's outfit should also include the following: (a) Sampling appliances. (These will be described later on). (b) Prismatic compass, 3 inches in diameter, preferably provided with metallic card. (c) Pocket compass, geological pattern. (d) Level. (e) Measuring tape, 50 feet or 100 feet. (f) Where practicable, a photographic camera, if only a kodak.

When once on the ground, the engineer will find it advantageous to pursue the following course of procedure, although it must be clearly understood that circumstances alter cases. The suggestions given here are general rather than special, and must be modified to suit the needs of each case:

(a) Carefully examine the mine plan. Get the mine manager to explain the general scope and extent of the underground workings.

(b) Examine the surface outcrops, if any, and note the geological and physical features.

(c) Examine the boundary lines and carefully note their position with respect to the dip and course of the vein ore body or seam being worked in the mine.

(d) Note the relation of the underground workings to the surface boundaries.

(e) Have a look at the ore coming to the surface, also at the rock on the dump.

(f) Examine and make a note of the surface equipment, including mills and all metallurgical plant and appliances. When describing steam engines, give the number and size of cylinders, maker's name, pressure of steam carried by boiler, etc.

The first day or two is spent in getting your bearings, and becoming acquainted with the manager and noting what kind of a man he is. A few days occupied on the surface in preliminary work is generally time well spent. Make a note of any facts presented or offered to you. Do not note opinions, and on your side be careful to offer none.

(g) Examine the underground workings accompanied by the mine manager or his deputy. According to the extent of the workings, it may take a day or two to do this.

(h) Again examine the mine plans. You will be able to follow them intelligently from the information you have gained underground.

You have now reached the critical stage in your examination. You have next to determine the condition of the mine; and among the questions that will naturally come into your mind will be the following: (1) Is this a young mine with a prosperous future ahead of it? (2) Is this a young mine doomed to early exhaustion? (3) Has this mine reached its maximum point of production? (4) Is this an old mine approaching exhaustion? (5) Is this an old mine with "eyes picked out?" The answer to these questions is to be found in the quantity and value of ore in sight. Do not forget that in a vigorous, well-managed mine the development work will be commonly two years ahead of the mill.

(i) Go underground with your own assistant, and sketch out your scheme of sampling.

(j) Sample the mine in a systematic manner. This may take a week or several weeks, according to the magnitude of the workings and size of ore bodies. (The general principles of mine sampling are described in the section treating of "Mine Sampling and Ore Valuation.")

(k) Complete your surface investigations. Get mine returns of output of ore and values extracted, or of mineral shipped or exported, mining and milling costs, etc. Carefully verify doubtful points.

(l) Before leaving the district make as complete an examination of the neighboring mines as circumstances will permit, noting character of country, ore bodies being worked, general characteristics of said ore, output, returns, methods of treatment, costs of mining and milling.

On no account allow yourself to be hurried in your examination. Take your own time. Cultivate a deliberate temperament. Base your estimates on facts, but be sure of your facts; and in your report be careful to differentiate between facts and opinions.

Your next care is the assay of your mine samples, and in this you must be guided by local considerations. If you are a skillful assayer, it is preferable for you to hire an assay office for a day or two, supply your own fluxes, crucibles, etc., and perform your own assays; or your assistant will probably be able to do so for you. In whatever way the work of assaying is done, it is imperative that the results must be accurate and reliable.

(m) Plot your assay values on tracings of mine plans, and then consider the results.

The form of your report will depend upon your recommendations. Manifestly the property may be—(a) Rejected; (b) secured on option; (c) purchased at once.

If, in your opinion, the property should be rejected, it will be unnecessary to furnish elaborate details concerning it. But if you recommend its purchase, it will devolve on you to supply information upon the following points: (1) The situation of property, and its relation to any valuable or worthless

concerns in the vicinity. (2) Means of access, with particulars of roads, railways, waterways, distances from centers of population, etc. (3) The area, owners, and names of old claims, if any, included in the area; history, nature of title, labor obligations, etc. (4) Physical features, including particulars of rivers, mountains, forests, rainfall, water power available, etc. (5) General geological structure: detail the rock formations present, their probable age, relations, disposition and distribution. (6) Description of ore bodies or mineral deposits, with particulars as to their position with respect to boundaries of prospect; their dimensions, dip, strike, outcrop, etc. (7) Description of old workings, if any. (8) Character and extent of present workings. (9) Quantity and value of daily output of ore. (10) Quantity and value of ore in sight. (11) Method of treatment of ore, or of disposal of mineral. (12) The cost of mining and treatment. (13) Probable net profit per ton, and per annum, on a specified annual output. (14) Probable life of mine with a specified annual output. (15) Description of present mining and metallurgical plant and appliances. (16) Development work recommended, if any, and estimated cost. (17) Details of additional plant, if any required. (18) Recommendations as to management of property. (19) Schedule of prevailing salaries and wages. (20) Schedule of mine supplies required, and their cost delivered at the mine. (21) Local and general rates, import and export duties, insurance, income and other taxes. (22) Number of working days in the year. (23) Climatic conditions and prevailing sickness, if any. (24) Mining legislation of country. (25) Amount of working capital required to develop mine to a paying point.

(TO BE CONTINUED.)

### Cameron Pumps in the Brooklyn and Manhattan Tunnel.

The accompanying illustration shows the Brooklyn and Manhattan tunnel pumping station on the Brooklyn side in the tunnel, now in course of construction under the East river, the Brooklyn shaft being at Furman and Jaroleman streets, to connect the Brook-

in case of the flooding of the tunnel. The accumulation of water in the excavation is forced out of the air chamber by means of the air pressure through a pipe built within the bulkhead, the water thus falling to a sump outside of the wall, from which it is pumped to the surface, the lift being 60 feet. Owing to the water being very dirty and gritty the water cylinder of this pump is supplied with a removable iron bushing. The pump is operated by compressed air, the exhaust of which is delivered into the compressed air chamber of the tunnel, where it is again utilized.

W. I. Aims is the engineer in charge of the work for the New York Tunnel Co., and to him we are indebted for the foregoing information and illustration.

### New Carborundum Products.

Attention is being called to the utilization as a refractory material of carborundum, which is produced by fusing coke and pure silica in the electric furnace at Niagara Falls, says the American Manufacturer. As an abrasive carborundum has already established the reputation of being superior to emery by reason of the fact that 1 pound of the former equals 3 pounds of the latter, relatively speaking. From 8 short tons reported in 1893, the production of carborundum has increased to 5300 tons in 1904, while the price influenced by the larger domestic and European consumption has fallen from an average of \$2125 per ton to \$200 in eleven years. At present carborundum grains are quoted at 10 cents per pound and powder at 8 cents f. o. b. Niagara Falls, New York. The expansion in production and the large discount in selling are suggestive factors that indicate the competition of carborundum with emery carborundum, crushed steel and like abrasive materials.

In recent years several patents have been issued in this country and abroad for refractory brick, cement and other articles whose principal constituent is carborundum. Generally speaking, pulverized carborundum is mixed with a binder of clay, an alkali silicate and lime. In patents issued to the Carborundum Company (Great Britain, 9963 of 1904) and to Frank J. Tone (United States, 772,262), however, no

Cameron Pump in the Brooklyn and Manhattan Tunnel.

lyn subway with the Interborough Rapid Transit subway at the southern end of Manhattan island in Battery park. The overhead construction of the tunnel is shown with the sectional cast iron lining.

A Cameron regular pattern piston station pump, 14x10½x18 inches, of the light service type, is in position in the tunnel about 100 feet from the Brooklyn shaft. On the left hand side will be noticed a bulkhead, consisting of a solid brick wall built across the entire tunnel, and 3 feet thick, heavily braced with timbers, forming the compressed air chamber situated on the further side of the bulkhead, where the air pressure is maintained at twenty pounds per square inch. The tunnel is being driven by the pneumatic shield method. The entrance into the workings of the tunnel is through the two air locks shown in the view. The lower air lock, 6 feet 6 inches in diameter, is used for the exit of material, which is removed by cars on a trackway. The upper air lock is an emergency lock for use by the men in escaping

admixture is used, the cohesion required being attained by subjecting the superficially oxidized particles of crystalline or amorphous carborundum at a high temperature in an electric furnace.

Aside from the regularly shaped refractory articles, carborundum fire sand, specific gravity 2.7, mixed with No. 1 fire clay and a solution of sodium silicate, serves excellently as a coating or lining for brass, lead, copper or other high temperature furnaces. Advantages claimed in this direction are simple construction, by molding the entire lining into place, freedom from joints, and durability. Carborundum fire sand is worth \$1.05 per 100 pounds f. o. b. Niagara Falls, which is much less than the cost of ordinary fire clay.

As a mixture in steel (French patent 344,906, July 3, 1904), W. Kaufman and A. Bouvier state that the silicon carbide is introduced in equal quantities at regular intervals into the molten metal as it runs into the ladle or mold.

## Lodgepole or Tamarack Pine.

The lodgepole pine, which is known in the Sierras of California as tamarack pine, and in Colorado and Montana is sometimes called white pine, jack pine, pinon and scrub pine, bears the common name of "lodgepole" from the fact that the Indians used its long slender trunks as supports for their wigwams or lodges. Its geographical range is along the Rocky mountains from Alaska to New Mexico and westward to the Pacific coast. In the United States it is found in merchantable quantity and dimensions on the spurs and eastern slopes of the Rocky mountains throughout southern Montana, Wyoming and Colorado, in the Bitter Root mountains of Idaho, the Uintah range in Utah, and in the Big Horn mountains of Wyoming. The Bureau of Forestry is studying the species throughout this range of its best commercial distribution.

Lodgepole pine grows at all altitudes between 3000 and 15,000 feet above sea level. In the Gallatin mountains of Montana and in the mountainous country south and east of Yellowstone park it reaches its largest size at elevations between 4500 and 8000 feet. In Colorado, however, towards the southern limit of its range, the conditions which are necessary to its best growth are found between 9000 and 10,500 feet elevation.

Lodgepole pine is valuable, for one reason, because it grows on high mountain slopes, and also on old "burns," where other trees find difficulty in obtaining a foothold. It readily adapts itself to most diverse soil conditions, but thrives best where there is considerable moisture. Its roots accommodate themselves to the shallow soil common in the localities where it grows. At a very early age this tree produces cones in large quantities, and after it is ten years old the seed are generally fertile. The cones sometimes open and distribute the seeds as soon as they are ripe, though more commonly they remain on the trees for years with their seed carefully preserved beneath the scales. In many cases squirrels cut off the closed cones and hide them away in the ground. If a fire occurs before the seeds are eaten, it will cause the cones to open and set them free. As a rule, however, the cones of many seasons remain on the trees until a fire comes along, and, by heating them, liberates the seeds, when a dense growth of seedlings follows.

The wood of lodgepole pine is light yellow to nearly white in color, with a coarse but straight grain. It is soft and easily worked, and would make excellent finishing lumber were it not for the abundance of small though hard knots, and for its tendency to warp and check with seasoning. Without doubt the best use of lodgepole pine at present, and the one to which it is most largely put, is for railroad ties and mine props; but to be utilized with the greatest

profit for these purposes the timber must first be subjected to preservative treatment. The Bureau of Forestry has for some time been conducting in Montana and Wyoming exhaustive tests in seasoning and in preservative treatment of this pine, and a comprehensive bulletin on this subject is now in preparation.

During the season of 1903-4 between 1,300,000 and 1,400,000 lodgepole ties were cut, most of which were treated with preservatives. The cut of this season will exceed this number, and without doubt the use of lodgepole pine for ties will increase yearly. Trees between 11 and 14½ inches in diameter breast high are hewed; those larger are logged and sawed, as the hewers refuse to work them. When a tree reaches 11 inches in diameter it is mature for ties; this makes it possible to remove a quantity of material from the dense natural forests as soon as a number of the trees have reached that size, and thereby to stimulate the smaller ones to a more active growth. At the same time a new generation may be started in the openings from the seed of the felled trees.

Great quantities of lodgepole pine are also used for props in the numerous mines in the region where this tree grows. The timber is cheap and in its natural condition answers for temporary purposes in mine development; when well seasoned or treated with preservatives it may be used for permanent con-

struction. Miners use poles as small as 5 inches in diameter at the top, and this demand for small timber works another advantage to the forest in that it offers a means of utilizing the upper parts of trees cut for lumber, which in the ordinary way of logging are left on the ground to become dry and increase the danger of fire. It also makes possible the thinning of pole stands which contain few or no trees large enough for ties, but which are so dense that the trees have almost stopped growing. The accompanying illustrations show the characteristic growth of the tamarack trees in the high Sierra of California.

By far the larger part of the merchantable lodgepole area is within existing or proposed Federal forest reserves, where the lumbering regulations which the Government put into effect some time ago will protect and benefit the forests.

Other objects of the Bureau of Forestry in this study are to ascertain the rate of growth of the tree, and how it may be increased; to better existing lumbering regulations; to devise a system of fire protection; and to extend the commercial uses of the wood. A controlling consideration is the need of maintaining the forests on all the mountains they now cover and of causing them to spread more widely, if possible, since the most important function they can perform is to safeguard the watersheds they include. This study will enable the Bureau to carry out more effectively the work of forest reserve management lately intrusted to it by Congress. The results of the study should also prove of large value to railroads and private owners, who hold a great many odd sections of land all through the lodgepole pine region.

For good behavior in construction, cement must possess two essential qualities—strength and soundness—says W. P. Taylor in the American Manufacturer, and the primary object of all testing is to determine whether the cement is satisfactory in these two important particulars. The other tests of fineness, specific gravity, time of setting and chemical analysis, are chiefly of value as the results give additional information as to probable strength and durability of the material. The precision and accuracy possible in any one of the physical tests vary inversely with the importance of that test. Thus, soundness is the most essential quality, and yet the ordinary tests for soundness are the most inexact and the most dependent upon personal judgment. In the tests for strength we have all the errors due to the personal equation of mixing, molding, handling and breaking, which make this test one of experience. In the time of setting these inaccuracies are still further reduced on account of the simpler processes required. In the fineness test, which is less important than the preceding, we reach the first test capable of some accuracy, and in specific gravity, which in itself has almost no importance, we reach the only test that can be considered capable of precise determination.

## Effect of Salt and Bluestone on Mercury in Pan Amalgamation.

Written for the MINING AND SCIENTIFIC PRESS by  
A. E. DRUCKER.

There has been some doubt whether bluestone and salt were really needed with the pan process in treating silver ores. It must be remembered that salt and bluestone are only necessary when silver sulphide ( $\text{Ag}_2\text{S}$ ) is present in the ore so as to change it into the chloride ( $\text{AgCl}$ ), in which form it can be readily reduced and amalgamated. Ores containing silver in the form of chloride only or native silver do not require bluestone. I believe salt is always beneficial, as it greatly increases the reduction of  $\text{AgCl}$  by iron, on account of the chloride being somewhat soluble in salt and increasing the surface of attack for the iron. The fine iron particles—caused by the wearing of shoes upon the dies—certainly are very important towards reducing the  $\text{AgCl}$  to metallic silver.

It is understood that the following reactions take place in a pan, and they show the need of bluestone and salt with ores containing sulphide of silver:

Cuprous chloride acts on any unchanged silver sulphide, as:

Equation (3) is the main reaction towards reducing  $\text{Ag}_2\text{S}$  to  $\text{AgCl}$ . Now the part the iron particles play is shown in the following reaction:

Also, to a slight extent, mercury reduces  $\text{AgCl}$ , or that portion which is soluble in a strong solution of salt, as:

The silver is then amalgamated. I may go on and give many other reactions, and I believe there is no limit to them, but these are the most important ones that do take place.

Large losses of quicksilver occur through flouring, when large excesses of bluestone are used in the pans—more than is needed to convert the  $\text{Ag}_2\text{S}$  into  $\text{AgCl}$ . This has been one of the main sources of trouble in most mills, more bluestone being used in the pans than is really necessary. The amount of bluestone for each charge day by day is told by a simple test on the amalgam obtained. Take an average sample of the amalgam (1 gram) and dissolve in 3 c.c. of strong nitric acid. Add ammonia until a blue color is shown. Regulate the bluestone so as to always have a faint blue color. By doing so, a very pure bullion and a better extraction will be obtained. Large excesses of bluestone are harmful to the amalgamation of free gold.

An excess of cupric and cuprous chlorides causes a flouring of the quicksilver, coating it with a film of chloride of mercury ( $\text{HgCl}$ ), thus preventing finely divided mercury from uniting. This may be plainly seen by trying an experiment in a bottle with mercury, bluestone, salt and water and shaking well. As I have said before, the mercury will be subdivided and the subdivision will continue with agitating until floured quicksilver results. The particles of mercury are coated with a dull gray film of chloride (calomel). The coating formed by boiling mercury with a bluestone solution is not the same. It must be a sulphate of mercury film. Now the same thing is bound to take place in a pan where a large excess of bluestone is used. The ore is charged into a pan and water added to give it the proper consistency; next an excess of salt (20 pounds) is added, and the required amount of bluestone—with Tajo ore 12 to 16 ounces. The miller is lowered so as to grind for a certain length of time, and it is during this period that the chemicals are supposed to do their work of changing the silver sulphide over to the chloride ( $\text{AgCl}$ ). The bluestone no longer remains as  $\text{CuSO}_4$  sulphate, but is changed to  $\text{CuCl}_2$ , as shown in equation (1) above. When  $\text{CuCl}_2$  acts on  $\text{Ag}_2\text{S}$ , cuprous chloride ( $\text{Cu}_2\text{Cl}_2$ ) is formed, and it is the action of either of these chlorides of copper—not the sulphate ( $\text{CuSO}_4$ )—on mercury that causes the calomel film ( $\text{HgCl}$ ) to form on quicksilver particles, causing flouring. I have made an analysis of some of this coating and found it to be the chloride of mercury. This chloride was found with the Comstock tailings, and, after cyaniding, considerable mercury was saved. The chloride could be saved by cyaniding but the floured mercury could not.

In my article published in the MINING AND SCIENTIFIC PRESS on April 15th last I spoke of zinc amalgam being used as a means of destroying the calomel film, causing floured mercury to reunite. Zinc amalgam also cleans mercury and causes it to be very active. It seems to act in the same way as sodium amalgam on quicksilver. Since copper sulphate is charged into the pan with a large excess of salt and is changed into cupric chloride shortly, then zinc chloride ( $\text{ZnCl}_2$ ) must be the result of the reaction of zinc amalgam on the calomel film as:

You cannot prevent the chloride of copper in solu-

tions from being reduced by any fine iron particles to metallic copper, especially if large excess of bluestone are used in the pans. The reduced copper is readily amalgamated by the quicksilver, and I will say again that only a slight excess of bluestone should be used in the pans over that necessary to convert the  $\text{Ag}_2\text{S}$  into its chloride. Large excesses will only result in very base bullion and low extractions. Mercury charged heavily with copper readily becomes coated by iron particles, and in the pulp it is readily coated by iron pyrites, lead and slimes. Any substance coating the mercury and keeping it dirty will interfere with amalgamation and increase the loss of quicksilver. I don't believe that mercury full of copper, which is bound to make it sluggish, can do good work. It only crowds out the precious metals.

While treating fresh and oxidized concentrates I found that the amalgam obtained from working old oxidized concentrates was quite pure, with very little copper, while that obtained from fresh concentrates was base, with copper. Now the only reason I can give for this, that in cases of oxidized concentrates the iron particles (from wearing of shoes and dies), contained within the concentrates were oxidized to ( $\text{Fe}_2\text{O}_3 + \text{H}_2\text{O}$ ), and in that form could not reduce the copper chlorides in solution. Hence we got practically pure amalgam, the copper remaining in solution as a soluble chloride ( $\text{CuCl}_2$ ) unreduced. But with fresh concentrates just from the mill and containing plenty of iron particles unoxidized, the copper chloride solution was reduced to metallic copper and amalgamated, giving naturally coppery amalgam.

The question has been asked, What class of ores does the bluestone help to amalgamate? All silver ores containing silver in the form of sulphide ( $\text{Ag}_2\text{S}$ ), and in this case it is very necessary. Bluestone does no good in the case of silver ores containing all the values in the form of silver chloride ( $\text{AgCl}$ ) or metallic silver; it only does harm in this case. The pan amalgamation process certainly can be improved upon, and it has by no means reached a state of perfection.

## Methods of Mine Timbering.

TO THE EDITOR:—As some of your readers may possibly be interested in a description of the methods of timbering as carried out in the Furness hematite deposits (in the north of England), where the writer

ing the ore is continued, the surface is allowed to subside and gradually follow the mining operations as they are continued downwards. The timbers most generally used in the district are larch and Swedish and Norwegian pine, but American pine is often used for shaft timbers and head frames. The method of supporting the main levels is by two props locally termed "forks," 7 feet long, supporting a cap 9 feet long, called "headtree." These timbers are 9 inches in diameter and form a set, and are spaced at intervals of from 12 inches to 3 feet center to center, according to the character of the ground. The props are faced or collared, i. e., hollowed out as shown in sketch, to allow the cap to receive a full bearing surface. To guard against side pressure a wooden plug called a "nog" is driven into the cap, close to the face of the prop, and when the side pressure is great a 9x3-inch stretcher is firmly wedged between the props and close to the caps for additional security. The workings must be timbered within 3 feet from the face. Spiles 1x4 inches cut into regular lengths are driven over the caps, to hold back the loose ground, old timbers and clay forming the roof. Where the ore is soft spiles are also driven behind the props at the sides of the level. When breaking out a new height of workings, in order to make more working faces, side workings are turned off (as shown in Fig. 1) at regular intervals, and the ore is split up into pillars. A heavy cap c (Fig. 1), called an "uptaker," supported by suitable props, is put in under the ends of the caps, at the side of the level from which it is intended to turn off the new working. This "uptaking" set usually takes in and supports four caps, and the two center props are removed after the uptaker or heavy cap is firmly fixed in position. Raises are put up vertically through the ore, and are usually 6x4 feet in the clear, with two compartments, one division being used for hoisting or lowering timbers, also for manway, ladders being placed at convenient angles and platforms at regular intervals. The raises are timbered with 5 and 6-inch square Norway pine, and between each set of timbers a 3 inch block is inserted at the corner, so that a space is left between each set to put a stage plank should it become necessary to repair the raise at any future time. The method of boring a hole in the cap, and fixing nogs to support the props, is very simple and effective, but there is no doubt it has the effect of weakening the cap and has often been criticised.

Side Workings.

Main Level.

Raise to Caved Workings.

spent five years as superintendent, the following is offered: These ore deposits are basin-like in form, surrounded by and enclosed in a hard, compact limestone, and have a covering of glacial drift, locally called "pinel." This covering varies from 60 to 200 feet in depth, and is boulder clay. The ore being soft and gravelly is worked from the top of the deposit, immediately under the clay roof, downwards until the bottom is reached. As the work of extract-

Some years ago the square-set method of timbering was adopted at one of the larger mines in this district, where the deposit was 120 feet thick, and was found highly successful where the ore was hard and compact, but it did not answer in the soft gravelly ores. This method was finally abandoned in favor of the one previously described.

Butte, Mont., May 2.

## Mines of Bisbee, Ariz.

The largest producer of copper in the Southwestern United States today is the Warren district, of which Bisbee is the center. The mines are mostly in the vicinity of Bisbee, and the reduction works at Douglas. Up to 1880 Bisbee was considered a lead camp, the principal mine at that period being the Hendricks, just south of the present town. The mine produced lead carbonate, which was smelted in a small furnace built where is now the main street of the village. The Copper Queen mine, to which is due most of the large copper production of the district and also its fame, was discovered in 1877 by Hugh Jones, who, however, failed to realize its worth and allowed his claim to go by default, it having been relocated by Geo. Warren and some others. It is said that later Warren wagered his share of the mine on the result of a foot race and lost. Such is the fortuitous experience of many a prospector. In 1880 an option to purchase the mine was given to Ballard, Martin & Reilly, and they at once began operations. After a little work a large body of rich copper ore was opened and the ore was worked by open-cut method. Later an incline was sunk to a depth of 300 feet in solid ore, and thus began the de-

Some of the Mines of Bisbee, Arizona.

velopment of one of the most noted ore bodies in the world. The first reduction plant consisted of two water jacket furnaces, 36 inches diameter, and with these, using wood as fuel, about 500,000 pounds of copper were produced monthly, from ore which

averaged 23%. The ore was self-fluxing, there were no sulphides, and it was one of the simplest metallurgical problems to be found in the West, paying largely from the day the furnaces were blown in. The mine continued to make a large and steady production from this original ore body up to 1884.

The Neptune mine, situated just east of the Copper Queen, began work at about the same time as the latter, and had a single furnace on the San Pedro river at Hereford.

Other companies were soon afterward organized to work various properties of the district, prominent among which were the Copper Prince and Atlanta. Benson was at first the nearest railway point, and all freight was taken to the mines by teams.

In 1884 the first ore body opened in the Copper Queen mine was exhausted at the 300 level, but after a little exploratory work a second ore body was found in both the Copper Queen and the Atlanta mines. The properties were then consolidated as the Copper Queen Con. M. Co., and soon thereafter the property of the Copper Prince Co. were added to the holdings of the Copper Queen by purchase, followed later by the absorption of several other mines of the vicinity. In 1884 the average value of the

Calumet & Arizona, Bisbee, Arizona.

View of Bisbee, Arizona, in 1880.

ore was about 12%, the metal selling at that time in New York at 18 cents. In 1886 three new 36-inch furnaces were put in to replace the old ones, and an 80-inch furnace was also built. After this, the larger furnace giving the greater satisfaction, the size of furnaces was increased from time to time. Concentration was tried with favorable results, but the jigs were afterward abandoned. As the work of mining continued the rich ore deposits at and near the surface were gradually exhausted, and as the workings went deeper the ore became lower and more base, as the sulphide zone was entered. Transportation expense increased and it was determined in 1887 to build a railroad, and accordingly grading on the roadbed was begun in that year to connect Bisbee with the Southern Pacific at Fairbank.

The metallurgical problem became daily more important as the percentage of sulphide ore continued to increase and the oxidized ores to become more scarce. Con-

verters were introduced in 1892, and matte smelting and conversion of the matte became the process at these properties.

Up to 1900 the Copper Queen combination was the only important producer of copper in the district, but about that time the Calumet & Arizona Co. came into the field and in the four years following developed a large and valuable property, proving that, although first in the field and with a vigorous career extending over a period of twenty years, the Copper Queen Co. had not found all the copper-bearing ground in that district. The Copper Queen Co. built a new line of railway, the El Paso & Southwestern, connecting Bisbee with El Paso, Tex., a distance of 240 miles.

The smelters at Bisbee becoming too much cramped for room, both the Copper Queen and Calumet & Arizona companies built new and extensive reduction works at Douglas, 26 miles from Bisbee.

Two of the accompanying illustrations show views of Bisbee. The other two show the Copper Queen and the Calumet & Arizona mines with their extensive surface equipment. The hills were formerly covered with junipers and oaks.

Bisbee, Arizona, in 1904.

## Cyaniding Copper-Bearing Gold Ores.

The treatment of siliceous gold-bearing ores, in which no elements are distinctly recognized as detrimental to the cyanide treatment of ores, has made great advancement since it was first introduced about fifteen years ago. Knowledge has been gained by a broad and constantly increasing experience, and also to a great extent through the careful and exhaustive research and experimentation of specialists in this department of metallurgy. Ores containing copper in any other form than the unaltered fresh sulphide (chalcopryrite) have, however, been recognized as offering many drawbacks to the successful application of the cyanide process in extracting the gold values contained in such ores. For years it has been known that ammonia, when associated with cyanide of potassium solutions, had a desirable effect in the treatment of gold ores containing copper. As early as 1884 J. W. Simpson filed application for a patent to treat gold-bearing ores by the combination of potassium cyanide, ammonia and salt. The language of his patent application is in part as follows:

To carry my invention into effect, I first grind or crush the ore containing the metal to be extracted to a powder of more or less fineness. This powder is then treated with certain salts in solution adapted to combine chemically with the metal in said ore and form therewith a soluble salt. After thorough agitation to mix the solution with the ore, the mixture is allowed to stand until the solid matter is settled and the solution has become clear. I then suspend a piece or plate of zinc therein, which causes the metal dissolved in the salt solution to be precipitated thereon, from which it can be removed by scraping or dissolving the zinc in sulphuric or hydrochloric acid. The precipitated metal may then be melted into a button.

The salt solution I use for dissolving the metal from the ore is composed of one pound of cyanide of potassium, one ounce carbonate of ammonia, one-half ounce chloride of sodium, and sixteen quarts of water, or other quantities in about the same proportions.

This solution is particularly adapted for ores containing gold, silver and copper in the form of sulphurets.

For an ore containing gold and copper only I use cyanide of potassium and carbonate of ammonia about in the proportions named.

For ores rich in silver I employ a proportionately larger quantity of chloride of sodium.

I am aware that cyanide of potassium, when used in connection with an electric current, has been used for dissolving metal, and also that zinc has been employed as a precipitant, and the use of these I do not wish to be understood as claiming, broadly.

I am also aware that carbonate of ammonia has been employed for dissolving such metals as are soluble in a solution thereof, and the use of this I do not claim; but what I do claim as new is:

The process of separating gold and silver from their ores, which consists in subjecting the ore to the action of a solution of cyanide of potassium and carbonate of ammonia, and subsequently precipitating the dissolved metal, substantially as set forth.

There are other processes all more or less intricate and involving numerous complex chemical reactions, in which ammonia and other salts and acids are employed with cyanide to extract gold from ores in the presence of copper. Among these are the leaching of the copper from the ores by means of sulphuric acid prior to the treatment by cyanide. This process is always more or less difficult, owing to the remaining copper and the acidity of the pulp, notwithstanding the washing with clear water. It always requires a greater or less amount of alkali to neutralize this acidity.

By another method, Scrymgeour's, the copper is leached out by means of a cupriforous cyanide solution, the copper being recovered electrolytically. The gold is then extracted by the ordinary cyanide solution and recovered also electrolytically.

Another method is that of leaching out the copper by means of ammonia, and subsequently, after washing, the sands are leached by cyanide solution. The copper and ammonia are recovered by distillation.

By the Bertram-Hunt method the pulp is treated by a solution of potassium cyanide and ammonia hydrate, the gold, and part of the copper, being extracted and recovered electrolytically, the gold, silver and copper present falling to the bottom as a fine precipitate or sludge, and may be treated in a filter press.

The Bagdad-Chase G. M. Co. at Camp Rochester on the Mojave desert, in San Bernardino county, Cal., have undertaken somewhat of an innovation in the treatment of its ores, which contain gold, silver and copper. The ore is an altered volcanic rock, probably rhyolite, more or less silicified and containing considerable iron oxide, copper carbonate (malachite), and silicate (chrysocolla), with gold values running \$20 to \$60 per ton and sometimes higher. Their mill is on the Santa Fe railroad at Barstow. This ore, after crushing, is treated by leaching in a strong solution of cyanide, which dissolves the gold and silver and also the copper. The gold is precipitated in the usual manner on zinc, the solution being kept strong to prevent as far as possible the precipitation of copper on the zinc. The solution, free from most of the gold, passes from the zinc precipitation boxes to a tank in which the copper is precipitated by means of zinc dust, the amount of which is care-

fully calculated and is introduced in proportion to the amount of copper present in the solution. Agitation is found necessary and is continued for several hours, until precipitation is complete.

In the treatment of the ore in the leaching tanks one pound of ammonia chloride and one pound of slacked lime are added to each ton of ore in the charge. In this process it has been found in practice that the amount of zinc dust required to precipitate the copper is from 100% to 150% of the weight of copper present in the solution, and by it the copper is almost completely recovered and the cyanide solution regenerated to a considerable extent for reuse, provided the zinc dust be free from zinc oxide.

## Electrical Rock Drill.

The Redfield all steel electrically driven rock drill, illustrated herewith, is the invention of J. H. Red-

Redfield Electric Drill.

field, 1735 Blake street, Denver, Colo. This machine is made of steel and can be operated on column and arm or tripod, and, according to the manufacturer, it requires but 1½ H. P. to operate. The motor is attached to the drill. There are but two working parts inside the machine besides the rotating mechanism. The machine proper weighs 175 pounds. The motor, which is attached to the drill and which can be readily removed, weighs 100 pounds and has 1½ stated H. P. capacity. The motor is manufactured of steel and is claimed to be water proof, and has ball bearings. This drill is being manufactured and placed on the market by Redfield Drill & Supply Co., 1735 Blake street, Denver, Colo.

## Gold Saving in Dredging.

The following is a brief extract of an article by H. L. Lewis in the London Mining Journal on recent practice in gold dredging in New Zealand:

AMALGAMATION A MISTAKE.—I found, while in Australia, a great craving among sluicing and dredging men for indiscriminate use of quicksilver. I have seen men, during the time a 6-foot box would be running its hardest, full of water and material, pour 50 pounds of quicksilver into the sluice and walk away quite satisfied, without the slightest thought or concern as to where it would go. Those who know the action of quicksilver and its peculiarities can have some idea of what became of it and any fine gold it may have picked up while on its course out at the tail of the boxes. Quicksilver, when indiscriminately used in this way, is not only wasted, but steals gold, and rolls on until finally buried in the tailings dump. It is claimed by some that quicksilver will save fine gold which would be otherwise lost. This is a matter of opinion. It certainly lessens the specific gravity and makes gold much more lively than it would otherwise be, which gives it a greater tendency to travel.

The best saver of fine gold I know of is the old perforated plate, made with slots and holes—the plate not more than 9 to 12 inches wide, with a riffle set at the back of each plate according to the fall of the box or floor. If the grade is 1 inch to the foot, make the back riffle ¾ inch deep, carry the plate over the following one sufficiently far enough to allow the sproggle set into the edge of each plate to rest on the top of the one below it, making the sproggle high enough to give ½ inch space from the bottom plate to the top one. When all the plates are set the whole becomes a series of small steps, similar to stair treads with ½-inch rises. The plates should be made of ½-inch steel or iron—steel for preference—drilled

or punched with ¼-inch holes, four to the inch. It will be found, when all plates are set, that each one is almost on a dead level, yet the fall of the floor and the grade of the run is 1 inch to the foot. The action of the system is to give to all stones and debris practically 75% of the whole sufficient fall to run away to the dump at the 8% grade—1 inch in 1 foot—while the gold, concentrates and fine sand pass through the perforations, the action of the water passing through with it keeping the fines alive without undue pressure, and the gold gravitates to the bottom, while the fine sands pass out under the space between the two plates and go through the same process over and over again, according to the length of the run. It will be found after the material has passed over the plate run very little fine gold has been lost. I have saved gold by this system that I have been unable to keep from floating on top of the water when panning off in a dish. Another advantage about the plate system is that the plates can be thrown back and concentrates taken up and placed ready for the laboratory in a few minutes. It gives the advantage of being able to clean, if necessary, the top run every evening. I have taken up 50 feet, had plates reset, and all going again in twenty-one minutes. This I claim as the best riffle of my experience for saving fine gold. Next comes expanded metal, which, laid on cocoa matting, is a most excellent gold saver, but in sluice runs must be protected by grizzlies, as the constant action of heavy stones passing over quickly wears it down. Expanded metal on dredger tables will always hold its place as a gold saver.

The gold mentioned would pass through 150 mesh. It is very unwise to cast away black sand or concentrates. I have known seemingly useless black sand and concentrates to give by fire assay 591 ounces 7 pennyweights of gold per ton. The closer we can stick to nature in gold savers the greater efficiency.

## THE PROSPECTOR.

The prospector can not afford to go into the hills with a preconceived notion. He must investigate every occurrence of mineral and test, as far as he is able, every kind of rock and formation, condemning none, for gold as well as other minerals is found in almost every kind of rock.

The mineral samples from Descanso, Cal., are of the same character—mispickel (a composition of iron, arsenic and sulphur). They may contain gold. Ore of this class is difficult to treat. It may be roasted in furnaces of proper construction to obtain the arsenic and the tailings treated for gold, if any be present, by bromo-cyanide. The gangue mineral is principally quartz. The yellow mineral is the result of the oxidation of arsenic. The ore should be assayed to learn the gold content. It may be found to be high grade enough to ship, and, on the other hand, it may be nearly or entirely without gold.

The mineral sample sent from Stockton, Cal., and marked W. D. B., is illmanite, also called menaccanite. It is titanite iron ore. It possesses the characteristic structure occurring in thin plates or laminae.

The mineral from Gilmore, Idaho, dark brown, with submetallic luster, is an impure specular iron, a variety of hematite.

The rocks from Homestead, Or., are: No. 1 is a dolomitic mineral, with scales of mariposite; rock of this character is common in some portions of the California gold belt. No. 2 is quartz, with a copper-iron mineral and a little copper sulphide; the blue color is due to azurite (copper carbonate), the brown color to iron oxide.

The rocks from Sheridan, Mont., marked D. G. D., are: No. 1 is bluish quartz, with pyrite. No. 2 is vitreous quartz stained with iron oxide; on one edge of this rock appears some red jasper.

The rock samples from Glacier Bay district, South East Alaska, marked H. M. O. are mottled marble. The texture of the marble is good, though the colors are not very bright. Possibly when developed to greater depth the quality may improve, that is be free from flaws, cracks, etc.

The rocks from Berkeley, Cal., are found to be No. 1, the blue rock glaucophane schist; No. 2, a gray schistose rock with bright shimmering plates, is talc schist in which also appears some glaucophane; No. 3 is a dolomitic mineral containing scales of the micaceous mineral known as mariposite; No. 4, the pink mineral, is largely silica.

The mineral specimens from Isabella, Cal., are: No. 1. Magnetite (magnetic iron oxide), with epidote (yellowish green mineral), quartz and feldspar. No. 2. Hornblende. No. 3. Dacite (a quartz-bearing hornblende andesite).

# Mining and Metallurgical Patents.

PATENTS ISSUED MAY 9, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS

PROCESS OF REDUCING METALS FROM THEIR SOLUTIONS.—No. 788,584; C. B. Jacobs, East Orange, N. J.

Process of separating gold from base metals, in cyanide solutions containing gold and base metal, consisting in subjecting solution to action of gaseous phosphide of hydrogen, in presence of free acid, thereby precipitating gold while retaining the base metal in solution.

BUCKET CLIP FOR AERIAL WIRE ROPE TRAMWAYS.—No. 788,674; B. C. Riblet, Spokane, Wash.

In rope and bucket clip, plate including bolts connected to plate and arranged to clamp plate to traction rope, wrist pin on plate, socket bearing having lateral opening and pivotally mounted on wrist pin, and pivotal connection between socket and tramway bucket.

COMBINED SMELTING AND REFINING FURNACE.—No. 788,546; C. C. Medbery, New York, N. Y.

Combination with heating chamber, of means for rotating, means for setting in different angular positions, fuel-supplying device connected to one end of the chamber, movable therewith and adapted to supply fuel to chamber in all of angular positions and while it is rotated; and opening at other end of cylinder.

MECHANISM FOR SHARPENING ROCK DRILLS.—No. 788,919; W. P. Lightbody, Johannesburg, Transvaal.

Machine of character described comprising rotary

support, series of fullers mounted thereon and having successive striking surfaces arranged in relatively different positions, means for rotating support, and means for holding drill in position.

PROCESS OF EXTRACTING METALS.—No. 788,912; J. A. Just, Pulaski, N. Y.

Process of extracting metals in form of metallic salts, from sulphide ores containing gold and silver, which consists in chloridizing ores, washing same to extract all water-soluble salts, adding acidified calcium-chloride solution of about 1.40 specific gravity thereto, chlorinating mass in presence of calcium-chloride solution, leaching with additional amount of calcium-chloride solution until extraction is complete, precipitating gold and silver with suitable substance, and separating precipitate from solution.

MINER'S PICK.—No. 788,719; W. W. Hoover, Penfield, Pa.

Pick comprising head having longitudinally tapered socket in one end thereof, with open-ended drift slot intersecting back of socket and extending entirely through head transversely of socket, pin permanently set transversely within head and projected into back portion of socket, and removable point having smooth tapered shank to fit socket and provided with seat to receive projection and constitute guide for proper positioning of point.

ORE ROASTER.—No. 789,371; J. W. R. Laxton, Lyon, Mass.

Ore roaster, consisting of drum revolving on horizontal axis, ore receiving pockets in periphery of drum, heat producing means within drum, hood

located over drum to receive fumes arising from ore being roasted, and hood located to receive products of combustion from fire within drum.

DEVICE FOR TREATING SLIMES.—No. 789,325; R. A. Kerr, Salt Lake City, Utah.

Device for treating slimes consisting in water-tight tank having inclined floor and vent at its lower part, vertical strips on sides and ends of tank, downwardly curved frame in lower part of tank, transverse strips across frame aligning with vertical strips, filtering fabric covering interior surface of all of strips, horizontal revoluble shaft extending through tank and blades on shaft adapted to rotate in curved frame.

ORE ROASTING FURNACE.—No. 789,303; P. A. Wagner, Carrville, Cal.

Combination with ore roasting apparatus, of collecting chamber interposed between roasting chamber and furnace stack, conduit for conveying hot products of combustion into collecting chamber, of means for maintaining water level within chamber above discharge end of conduit during working of ore, and pipe extending from outside of collecting chamber into discharge conduit of roasting chamber, through which pipe inspection of interior of roasting furnace may be had.

APPARATUS FOR DISTRIBUTING MOLTEN SLAG IN BLAST FURNACES.—No. 789,133; R. Baggaley, Pittsburg, Pa., and C. M. Allen, Lolo, Mont.

Blast furnace having ore charging opening and means located at different part of furnace for distributing molten charge in interior of furnace.

THE electric furnace possesses some important advantages over furnaces of ordinary type, the principal one being the very high degree of temperature which is available, making it possible to fuse substances which are infusible by any other means. It has been possible to make in the electric furnace minerals unknown in nature, for instance, carborundum. In the electric furnace mineral substances previously considered infusible are melted down without difficulty, and even volatilized.

THE new dam which it is proposed to build in the canyon of Salt river, near Phoenix, Ariz., will be a large affair. Its extreme height will be 270 feet. The overflow weir will be 210 feet above mean low water in the weir and the length of the dam at the spillway will be 780 feet. The reservoir is calculated to hold over 300,000,000 gallons of water. The dam is to cost \$1,147,000 and is to be built of rubble masonry.

"FUNNY how things go," says a San Francisco, Cal., mining engineer. "I am back from Montana drafting plans for a gold dredger to be built in Montreal for use in Colorado."

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Practically complete returns to the United States Geological Survey for 1904, as collected by E. W. Parker, statistician, show that the production of coal during 1904 amounted to 351,196,953 short tons, having a total value at the mines of \$445,643,528. Compared with 1903 this shows a falling off of 6,159,463 short tons. This decrease, although proportionately large, does not indicate any interruption to the generally prosperous conditions which have prevailed during the last eight years. It was simply a natural reaction from the abnormal activity which had been maintained throughout the coal mining regions in 1903, due to the exhaustion of all coal stocks on hand by the memorable strike of 1902. In order to renew the coal stocks and at the same time to provide fuel for immediate use, the coal mines in 1903 were pushed to their utmost capacity, or to the capacity of the railroads to handle the output. As a result the enormous production of 358,356,416 short tons was recorded. Prices raised high by the famine of 1902 remained high for a large part of the year, and the total value of coal at the mines, before any expense of transportation or selling costs had been added, amounted to \$503,724,381, an increase of \$136,600,000 over that of 1902. The production in 1904, while less than that of 1903 by 6,159,463 short tons, exhibits a normal increase when compared with the annual production during the ten preceding years. The average price for all coal mined and sold during 1904 was \$1.27, as compared with \$1.41 in 1903, and \$1.22 in 1902. The statistics for the production of anthracite in Pennsylvania, which are complete, show that the output in 1904 amounted to 65,318,490 long tons (equivalent to 73,156,709 short tons), valued, at the mines, at \$138,974,020, as compared with 66,613,454 long tons (or 74,607,068 short tons), valued at \$152,036,448 in 1903. The decrease in production in 1904 therefore amounted to 1,294,964 long tons (or 1,450,359 short tons), while the falling off in gross revenue amounted to \$13,062,428. Of the total production of Pennsylvania anthracite in 1904, 57,727,178 long tons were shipped to market, 1,410,703 tons were sold to local trade and employees, and 6,180,609 tons were used at the mines for steam and heat. The average price for the marketed product (excluding colliery consumption) in 1904 was \$2.35, as against \$2.50 in 1903. One of the interesting features in connection with the anthracite trade is the constantly decreasing proportions of the large or more profitable sizes of coal sent to market, and the equally constant increase in the proportions of small or less profitable coal. In 1890, 77% of the shipments from the anthracite regions consisted of sizes larger than pea coal, and 23% represented the shipments of pea coal and smaller. In 1904 the large sizes made up only 62% of the total, while the small sizes had increased to 38%. Or, putting it in another way, the total tonnage of large sizes from 1890 to 1904 has increased 25% (from 28,154,678 tons to 35,636,661 tons), while the tonnage of small sizes has increased 158% (from 8,460,781 long tons in 1890 to 21,855,861 long tons in 1904). The recovery of usable coal from the old culm banks by washing has furnished some of this increase in the shipments of small sizes, and the installation of washeries at the breakers for saving the small sizes in the primary preparation of the coal has done more. The recovery from the old culm banks has averaged about 2,500,000 long tons annually during the last four years. The statistics of bituminous coal production comprise all varieties except Pennsylvania anthracite, and include semianthracites, semibituminous, cannel, splint, and block coals, and brown and black lignites. The small production of anthracite in Colorado and New Mexico is also included in the bituminous output. In 1904 the aggregate production of all these varieties amounted to 278,040,244 short tons, valued at \$306,669,508, against 282,749,348 short tons, worth \$351,687,933 in 1903, indicating a decrease of 4,709,104 tons in amount and \$45,018,425 in value. The average price a ton for all coal mined and sold, including colliery consumption, fell from \$1.24 in 1903 to \$1.10 in 1904.

The following table shows the amount and value of the coal production of the United States in 1904:

State.	Production.	Value.
Alabama	11,168,194	\$13,356,065
Arkansas	2,009,451	3,102,660
California and Alaska	75,838	207,261
Colorado	6,594,295	9,604,228
Georgia and North Carolina	400,191	489,596
Idaho	3,380	12,330
Illinois	35,990,796	39,417,882
Indiana	10,929,908	12,068,097
Indian Territory	3,011,972	5,472,490
Iowa	8,542,005	10,555,169
Kansas	6,322,875	9,621,252
Kentucky	7,559,940	7,848,153
Maryland	4,816,171	5,723,774
Michigan	1,338,447	2,410,358
Missouri	4,187,197	6,872,126
Montana	2,197,408	2,197,408
Nevada	150	1,500
New Mexico	1,459,182	1,908,952
North Dakota	269,297	381,731
Ohio	24,415,054	26,522,090
Oregon	111,540	243,588
Pennsylvania	97,916,733	95,877,581
Tennessee	4,782,302	5,642,558
Texas	1,072,195	1,750,355
Utah	1,591,607	1,941,395
Virginia	3,578,002	3,087,232
Washington	3,135,757	6,115,863
West Virginia	82,332,385	28,818,698
Wyoming	5,177,351	8,741,970
Total bituminous	278,040,244	\$306,669,508
Pennsylvania anthracite	73,156,709	138,974,020
Grand total	351,196,953	\$445,643,528

### ALASKA.

J. K. Darnell of Breckenridge, Colo., writes to the Breckenridge Bulletin from Fairbanks, Alaska, that the ground is always frozen and that they sink from 12 to 150 feet to bedrock without a stick of timber, as it never thaws. The gravel that pays is from 2 to 10 feet on bedrock and is thawed out in the working shafts with steam from boilers which run engines and hoists. The ground is thawed by using points, which are pointed and hollow from near the butt to the point and are about the size of a drill. This point is driven into the frozen ground and steam forced through the hollow part. Wages are \$6 per day for teamsters and all expenses; but freighting is mostly done in the winter when the ground is frozen, as the top soil or muck which lies above the ground from 10 to 40 feet thick will thaw 3 or 4 feet deep. Board is \$80 per month in town and at the mines \$28 per week with lodging, and wages \$1 per hour. Freight to the mines, 25 miles away, is 5 cents per pound.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The successful run of the new 5-stamp mill of the Gold Nugget M. Co., near Bisbee, has caused the company to decide to add new stamps and concentrators. Two new hoists are also to be added. Work has been started at the Denn-Arizona at Bisbee. In Warren district the Saginaw, near Bisbee, is down 875 feet and work is progressing at the rate of 65 feet per month. A drift is being run on the 350 toward the old incline shaft to make an air connection. A double drum first motion hoist has been ordered. It will have a capacity to handle a load of 7500 pounds at a depth of 1400 feet. At the Shattuck & Arizona, at Bisbee, the drift on the 500 is in 130 feet. The shaft is down 665 feet. Water in the shaft continues to increase slowly and is making at the rate of 2000 gallons daily. The company employs twenty-six men. Bisbee, May 16.

#### Graham County.

(Special Correspondence).—The Coronado Copper Co. is putting in a new 25 H. P. gasoline hoist at shaft No. 2. The small hoist at present in use will be moved to another place where the work is lighter. J. S. Schofield is superintendent. Metcalf, May 15.

#### Mohave County.

J. Brockman, manager of the Commonwealth M. Co., operating the Pilgrim mine at Pyramid, 20 miles from Kingman, is crosscutting from the bottom of the 200-foot shaft and intends to continue sinking to a depth of 500 feet.

#### Pinal County.

(Special Correspondence).—In Kelvin, or Mineral creek, district the Big Lead M. & S. Co. is making a test run of 500 tons of copper ore in the Boh Tail mill, which the company has leased. It has also ordered a 100-ton concentrating plant and expects to buy the mill and begin active operations. Kelvin, May 15.

#### Yavapai County.

(Special Correspondence).—A new placer machine being put in by the International M. Co. on their claims on Lynx creek is said to handle 1000 tons of dirt daily, which is pulverized by a separate machine. It is forced by air through a series of screens. The gold, being heavier, drops into receptacles. Prescott, May 16.

On the Santa Maria river, west of Hillside, J. H. Hise has started a 900-foot tunnel to develop his vein near the Sultan mine. Work has been started on the Venture Hill and Black Hills group, near Jerome. Superintendent Davies of the Reliance Co., working the Sundance in the Hassayampa district, south of Prescott, is shipping concentrates regularly. It is expected that the sampling works of the new smelter at Val Verde will be running by Aug. 1. The machinery for the 600-ton smelter has been ordered. The main shaft of the Great Reliance mine, near Turkey, is down 540 feet.

It is reported that Manager C. W. Clark will put in a new 500-ton furnace and two copper converters at the United Verde smelter at Jerome. Smelter Superintendent Taylor has been making experiments with oil in smelting. The Decatur at Jerome has been unwatered and drifting commenced.

#### Yuma County.

The Arizona Sampling & Smelting Co. has been formed to establish an ore sampling plant in Yuma. The company expects to be ready to receive ore by July 1.

### CALIFORNIA.

It is reported that a war is waging between the Standard and Associated Oil companies and the Union Oil Co. for control of California oil. As a result of this condition the independent owners are said to be suffering. It is said that the Standard has formed a compact to squeeze out the smaller dealers and have been exchanging oil in Los Angeles and San Francisco, loading Associated oil and shipping from Los Angeles, while the Associated is loading from Standard tanks. They are selling as cheap, if not cheaper, than the actual cost of production. In the Coalinga oil field, although the Associated is paying 15 cents for crude oil, it is selling to local consumers for 65 cents a barrel.

#### El Dorado County.

Work at the Alcimonte mine, formerly the Granite, has been temporarily suspended pending the arrival of a new hoist. Operations will be resumed under the supervision of Chas. Henson.

The Oro Flamme mine, Diamond district, has resumed work. It is reported that a very rich body of ore has been encountered at the Pyramid mine, near Shingle Springs. It is reported that a heavier engine and new machinery it to be put in the Ida Mitchell mine, Placerville, and the shaft put down to the 1000-foot level. Work at the Granite mine, Smith's Flat district, is under the foremanship of C. Hanson. The new hoist is being put in.

#### Kern County.

The Gold King mine, Randsburg, is being developed

by H. W. Manly of Johannesburg. The shaft is down 80 feet.

#### Nevada County.

New hoisting machinery is to be put in at the Kenosha mine, Grass Valley, preparatory to deepening the shaft. New electric pumps are to be put in at the Bullion mine, near Grass Valley, to handle the heavy flow of water recently struck. The Union reports that the North Star M. Co. employs 384 men, the Empire 175, Pennsylvania 120, Sultana 55, Brunswick 50, New York-Grass Valley 37, and Idaho-Maryland 30.

J. McElvey of Oakland is opening up the Birchville and South Fork mines, near Graniteville.

#### San Joaquin County.

(Special Correspondence).—A. P. Bovier has returned from the general managership of the Oriental mines, Korea, and with G. W. Kimble is testing some property here with a view of putting in a gold dredger. Clements, May 18.

#### Sierra County.

F. Kuhfield has charge of work on the South Eureka mine, near Forest City, which is under bond to J. H. Hurin and E. G. Gardiner, both of Los Angeles. W. W. Tiner, superintendent of the Alleghany M. Co. at Balsam Flat, near Alleghany, has run the tunnel in 900 feet and is working on the second upraise to find the bottom of the channel, the first having struck the east rim. He has negotiated with New York people to bond the Young America mine, ½ mile southwest of Forest City. O. Owens has driven the tunnel of the Columbia Channel G. M. Co., near Forest City, over 1600 feet and hopes to strike the channel within 200 feet. J. M. Harper is manager. H. L. Johnson continues to take high-grade ore from the Tighter at Alleghany.

#### Siskiyou County.

It is reported that the New York mine near Fort Jones has been shut down. J. B. Scott, the superintendent, is in St. Paul, Minn.

#### Trinity County.

R. Hicks of Junction City has seven men working at the Hunter mine at New River City. J. Byers is working the Mountain Boomer, owned by the Bob's Farm M. Co., at New River.

#### Tuolumne County.

Excavations for mill foundations are being continued at the Horse Shoe Bend mine, near Columbia. Ore is being taken from the 90-foot shaft. At the Jumper mine twenty stamps are dropping. Superintendent M. D. Kelley is devoting his attention to development work. It is reported that Superintendent W. R. Hall, of the Bluebell M. Co., will start milling the ore from the Hardtimes mine at Arastaville.

### COLORADO.

(Special Correspondence).—The Colorado State Mine Operators' Association, with headquarters in Denver, realizing the importance of having a Bureau of Mines and Mining in the President's Cabinet at Washington, will work in harmony with similar organizations in other States. The association when first organized was made up of delegates or members from local associations throughout the State. On account of some of the mining districts not being in a position to support a local organization the State association has decided to do away with the original plan and make it a stronger and larger organization. W. E. Passmore, secretary of the association, says that the association has never and does not intend to use its influence in the political field. It is believed that when the operators throughout the State come to understand the needs and objects of the association they will not hesitate to become members and that within a short time a large majority of the operators will affiliate with the organization. "High grading" is still being carried on systematically in certain districts of Colorado. The question is attracting the attention of the operators and an attempt will be made to do away with the stealing. The card system which is now employed in several districts is said to be about the best remedy known. When a person is caught high grading his card is taken up and he is not permitted to work in the district in any of the mines without a card from the operators and in that manner the operators believe they have solved, to a certain extent, the high grading question. Decisions have been rendered that a person knocking down ore and catching it before it drops to the ground can not be considered as stealing as it is impossible to steal real estate. Should the ore drop to the ground or be taken from the ore bin it is considered stealing, but the question has been to prove the ore. The Telluride mill which was advertised for sale by Duncan Chisholm, trustee of the defunct General Metals Co., Colorado Springs, was not sold, as no bids were made, owing to the statement of the trustee that no bid would be received or considered for less than \$200,000. It is understood the same will be re-advertised for sale. The probability of the Burlington and Union Pacific roads making lower freight rates from Denver into Wyoming and the Black Hills is encouraging the manufacturers of mining machinery in Denver. Denver, May 16.

In a recent paper of the U. S. Geological Survey, N. H. Dalton says that "lignite coal occurs in the sandstone series that outcrop near the base of the Laramie formation along the foothills of the Front Range in a belt extending from near Greeley, 50 miles north of Denver, to Wildcat mountain, 25 miles south of Denver, and appears again after an interval of 50 miles near Colorado Springs. South there is coal in the northern portion of the Raton coal field in the Walsenburg-Trinidad region. Coal occurs in the Denver region 200 feet above the base of the Laramie formation in beds that are steeply inclined near the base of the mountains, but lie nearly level under the plains. At Scranton, 20 miles east of Denver, coal occurs in clays of the upper Laramie. The steeply inclined coals to a depth of 300 feet have a relatively higher specific gravity, but a lower fuel ratio than the prairie coals which resemble the bituminous coals of the East. The coal at Scranton in the upper Laramie is a true lignite with a high water content and a low fuel ratio. From Ralston southward the Laramie formation dips steeply at angles from 70° to

80°, and the outcrops of the coal-bearing portion of the series lie in a narrow band 250 feet wide. North of Ralston and east of Boulder the dip becomes more gentle and a succession of faults and folds brings the coal within profitable working distance over a large area. The coal is black, lustrous and breaks in blocks. The beds have a thickness of from 4 to 10 feet. The Scranton mine shaft shows two workable beds of coal, 6 feet and 7 feet thick, respectively, separated by 1½ feet of shale and sandstone, containing a 3-foot bed of coal. The Walsenburg-Trinidad region is the northern extension of the Raton field of New Mexico. The coal is found in the sandstone series at the base of the Laramie formation. Toward the south of this field in Colorado the coal is much changed or even destroyed by igneous intrusions. The excellent coking qualities of the coal in this region is thought to be due to these igneous intrusions. Near Walsenburg and Pitcon only the basal coals of the Laramie are worked."

King & Craig are successfully operating a cyanide plant on the Anaconda property at Cripple Creek. Besides treating the dumps of Gold hill, they are mining ore from the main Anaconda vein near the surface. The winze being sunk below the 400-foot level has reached a depth of 160 feet, which gives a total depth of 547 feet. Machinery has been put in the underground workings to handle the rock economically.—A lease has been granted upon the property of the Rattler G. M. Co. on Raven hill to J. Bussert of Cripple Creek and S. S. Childs. The lease is for two years and provides for the sinking of the main shaft to a depth of 500 feet. The lessees are putting in hoisting machinery and power drills.—The south block of the Agnes property on Beacon hill, Cripple Creek, has been leased to S. B. Inskeep. He proposes to sink 50 feet, giving a depth of 200 feet.—P. J. Fleming, leasing the north block of the Agnes, intends to put in a hoist and develop mineral indications at the 100-foot level.—F. Wilder and associates will resume work at the Fountain Valley shaft of the Banner Gold Co.

#### Boulder County.

The Summit mine, ½ mile above Salina, is to be worked soon. Nearby, the Fairfax, Clansie tunnel, Richmond and Ingram have been shipping.

#### Chaffee County.

Temporary suspension of operations at the Mattie C. mine, 7 miles north of Buena Vista, has been caused by a breakdown of pumping machinery at the mine, and twenty-five men have been laid off. The mine will be shut down until the repairs can be made.

#### Clear Creek County

W. Teagarden, manager of the St. Paul M. Co., has sold a controlling interest in the property to C. W. Miller of Osage City, Kan. The St. Paul vein is an extension of the Colorado Central on Green Lake mountain, near Georgetown, and is being developed by tunnel. The upper level is in over 1500 feet. Machinery will be put in at the base of the mountain to drive crosscut tunnel started recently.—The Pay Rock power plant, near Breckenridge, has been started and power drills are being used in the upper Pay Rock tunnel, being driven by C. I. Burt, who is endeavoring to cut the Vulcan lode at a depth of 300 feet under the old workings.

#### Gilpin County.

The Jo He tunnel, in Phoenix district near the mouth of Boulder park, has been started up under the foremanship of D. D. Johnson.—G. Mosch of Tolland has a contract for extending the Gold Run tunnel property, near the head of South Boulder creek. The main tunnel, which is a crosscut, is in 305 feet and the tunnel is to be extended several hundred feet.

#### Gunnison County.

The Southwestern smelting plant, 2 miles below Whitepine, has been leased and will be run by McArthur & Co. of Leadville. The plant is of fifty tons capacity. The mines of the district have ore in sight to keep the smelter running steadily.—The Raymond tunnel at Ohio City is in 2150 feet, has a vertical depth of 1260 feet and in this distance has cut fourteen veins, six of which are being developed. It is reported that a mill will be put up this season.—The West Gold Hill M. Co. is operating its 50-ton mill in West Willow Creek gulch, in the Tin Cup district.

#### Lake County.

Lead carbonate ore is being opened up at the Bessie Wilgus mine, Leadville.—A new shaft is to be sunk on the Buckeye, Fryer hill, Leadville, by Lessees Jenks & Finn.

G. H. Harlan will start work at his Mt. Elbert mine near Twin Lakes.—H. Hentschell is preparing to resume work at the Mt. Storm, Twin Lake district.—Work has been commenced at the Cache Creek placers by Manager N. A. Loggin of Twin Lakes.

#### Ouray County.

As soon as the damage done by the snowslide at the Bankers' Cons. mine, above Ouray, is repaired, work will be started on the crosscut tunnel, which is in 1265 feet. Considerable surface prospecting will also be done. J. McNeill is superintendent.

#### San Juan County.

The Silverton Standard says that four new tram lines are to be constructed in San Juan county this year. The Mogul will be 2½ miles long and the Gold Prince tram will be 10,000 feet. The Ross M. Co. are figuring on placing a line at their Galty Boy property, Cement creek, and Champion mines, Sultan mountain, while the Mayflower Co., as a possible fifth, contemplate connecting their mine with either the Contention mill, on the Animas river, or with a plant that will be built this summer. When completed these will make 21 miles of aerial tramway in the county.

#### Summit County.

C. Senter, superintendent of the Golden Clover Leaf Co., has resumed work on Fletcher mountain, near Breckenridge.—The Felicia Grace M. Co. of Breckenridge is enlarging its shaft and intends sinking to the second ore body.—The Jennie Queen Co. are pumping and sinking.—Preparations are being made to sink the Robinson Con. east shaft, near Breckenridge, 225 feet deeper.—The King Solomon M. D. & T. Co. of Frisco are putting in a new air compressor to hasten work on

the main tunnel. D. Myers is superintendent.—The Excelsior mine at Frisco is reported closed because of too much water.—Electric power is to be put in at the Admiral G. M. Co.'s mine, near Frisco.

#### Teller County.

The Golden Cycle Co. is preparing to build a 200-ton mill for the treatment of ores from its Cripple Creek mine.—The Regi group on Battle mountain, Cripple Creek, has been bonded for \$250,000, the bond and lease being in the possession of the Fortuna G. M. & L. Co., C. S. Kinney, president. They will extend the 200-foot level to cut an extension of the Portland vein.

Ore is being shipped from the Triumph mine on Battle mountain, Cripple Creek. This is being taken out through the main shaft of the Coriolanus. A crosscut is to be started from the 500-foot level of the Coriolanus to prospect the Triumph ground.—At a depth of 185 feet the 250-foot shaft being sunk by the lessee, C. G. Jackson & Co., on the Black Jack of the Anchor G. M. Co., has struck a good ore body.—Lessees Selbach, Johnson and associates, operating on the Pride of Cripple Creek on Ironclad hill, have ordered a new 80 H. P. boiler, an 8x10 hoist, and a 6-drill compressor. The shaft is down 150 feet and will be sunk to the 300-foot level before lateral work will be started.—The Clyde M. & M. Co. has granted to the Majestic Finance & Development Co. a bond and lease on its Bull Hill property. C. P. Schumacher has charge.—F. J. Buck has a contract to sink from 300 to 600-foot level of the Nugget shaft on Rosebud hill, Cripple Creek, under lease to the Kimball Investment Co. of Denver.—The Conundrum claim of the Anchoria-Leland Co., the Mary Ann claim of the Duchess Co. and the Ethel Louise claims Nos. 1 and 2 have been consolidated as the Ethel Louise G. M. Co. The claims are on the west slope of Gold hill, Cripple Creek. The deal has prevented litigation. The properties are traversed by the Conundrum vein and will be worked through the Conundrum shaft, now 800 feet deep. C. W. Howbert is general manager.

#### IDAHO.

##### Boise County.

(Special Correspondence).—A new mill is to be put in at the Osborne mine at Marsh. C. A. Devlan is manager at the mine.

Marsh, May 15.

##### Cassia County.

The Idaho Oil, Gas & M. Co. has been formed to prospect and operate oil and gas wells and coal mines in Goose Creek canyon, near Oakley. H. G. Carpenter of Pittsburg, Pa., will put in a boring machine with a 3300-foot capacity.

##### Idaho County.

The 40-stamp mill of the Sunnyside mine at Roosevelt has been started again.

##### Shoshone County.

The Success M. Co. has fifteen men at work grading for their new 100-ton mill and concentrator near Wallace, which they expect to have running by August 1. This will handle ore from the Granite property on Nine Mile creek and will save both zinc and lead concentrates.—Experiments have been made toward dredging Pritchard creek near Wallace.—The Handspike copper mine on Little North Fork continues to show good copper.—The Stewart mine near Wardner has resumed shipping carbonate ore carrying good values in lead and silver.—The New Jersey G. M. Co.'s flume on Big creek near Wardner, a part of which was carried away by a landslide, is being replaced.

Condemnation proceedings have been instituted in the Wallace district court by P. Larsen and T. L. Greenough, owners of the Morning mine at Mullan, against A. A. Headrick and C. M. Baillie. A tunnel, known as the Morning tunnel No. 6, is being driven by Larsen & Greenough. It has already proceeded 7605 feet, and it is the intention to continue driving it 1080 feet farther. By this tunnel the mine can be worked and developed to a depth of 2500 feet. Between the ore bodies and the mouth of the long tunnel are two claims owned by Headrick & Baillie, which are known as the Blackhawk and the Alvy claims. The complaint says it is necessary for the long tunnel to traverse these claims for 694 feet, at a depth varying from 1750 to 1900 feet, in order to reach the ore bodies. It is recited that the only successful and complete way to work the mine and drain it is by means of this long tunnel traversing the Blackhawk and Alvy claims. The plaintiffs allege that they have endeavored to acquire a right of way for the tunnel through the claims by agreement or otherwise and have been unsuccessful. A decree is asked from the court, condemning and awarding the plaintiffs a right of way through the two claims. They ask that three disinterested persons from Shoshone county be appointed to act as commissioners, who will assess any damage that may result. They desire to appropriate a space 10 feet wide, 12 feet high and 694 feet long. It is asserted in the complaint that no damage to the claims can possibly result, but that, on the contrary, they will be benefited. Headrick & Baillie recently instituted proceedings in the district court seeking to restrain Larsen & Greenough from continuing with the long tunnel. They later dismissed the action and transferred the case to the Federal court.

A dredger is being built on French gulch, near Pierce City, with a reported capacity of 400 cubic yards daily.

#### MICHIGAN.

(Special Correspondence).—Production by Lake Superior copper mines fell off in April, owing to the strikes which enforced suspension of operations at the Wolverine, Franklin and North and South Kearsage branches of the Osceola Con. mine. The total production of the district was 16,800,000 pounds of refined copper.—The Copper Range Con. Co. has a two-years' option on two sections of the Glohe property, on the south range, owned by John Stanton of New York. A vertical shaft will be sunk through the sand and boulders overlying the ledge, and crosscuts will be run in both directions from the bottom to cut the Baltic lode.—The Atlantic mine is stamping 950 tons of rock daily.—Preparations are being made for a compound stamp head at the Calumet & Hecla M. Co.'s stamp

mills at Lake Linden for experimental purposes. The Calumet & Hecla will put in two compound heads.—The Phoenix Con. Co. of Keweenaw county will prospect the Ashbed lode and the St. Clair fissure vein.—Surveys have been completed for a new shaft for the Rhode Island property.

Calumet, May 15.

#### MONTANA.

##### Fergus County.

The Judith Belle G. M. Co., near Gilt Edge, will start prospecting with diamond drill. — E. W. King is putting in an electric drill plant at the Barnes-King mine at Kendal.

##### Madison County.

The Revenue mill, near Norris, has resumed operations after being closed for two months. — The Montana & St. Paul M. Co. has reorganized as the Montana Overland M. Co. and will develop claims in the Wisconsin creek district, east of Twin Bridges. — The gravel in Goodrich gulch, 7 miles from Twin Bridges, is to be hydraulicked by the American Goldfields Co. of Spokane, Wash.

##### Silver Bow County.

(Special Correspondence).—The copper output of the Butte district for the thirty days ending May 13 was 34,400,000 pounds, the different companies being represented as follows: Anaconda, Parrot, Butte & Boston, Trenton and Washoe (Amalgamated), 18,150,000 pounds; Boston & Montana (Amalgamated), 5,850,000 pounds; United Copper, 3,900,000 pounds; Clark mines, 3,580,000 pounds; North Butte, 1,920,000 pounds. For two weeks the Parrot has been shut down by injunction, on which account there has been a loss from that source of 35,000 pounds a day. Reports from New York, from United Copper sources, are that negotiations for a settlement in the Montana war between the Amalgamated and F. A. Heinze have been renewed.—A strike of copper has been made in the Belmont (United Copper) mine, on which Heinze has been doing development work.—The average of Amalgamated ore yields sixty-five pounds of copper to the ton. North Butte shows an average of eighty pounds.—A rich strike of gold has been made in the Carbonate district near Monarch, Cascade county, on the claims of H. E. Randall.

Butte, May 15.

C. L. Geyman of Butte, president of the Geyman M. Co., has been sentenced to forty days in the county jail of Silver Bow county for violation of a restraining order issued by Judge H. Knowles in April, 1904. The case in which the sentence was imposed is that of the Butte & Boston M. Co. against the Geyman M. Co. and C. L. Geyman, the property in dispute being the Kane No. 1 vein. Judge Knowles issued an order restraining the defendants from extracting ores from this property. Some time ago application was made by the plaintiffs for an order citing the defendants to show cause why they should not be punished for contempt of court for violation of Judge Knowles' order. Judge Hunt issued the order to show cause and the defendant was found guilty. The Geyman M. Co. was also adjudged in contempt and fined the cost of the proceedings.

#### NEVADA.

##### Esmeralda County.

Superintendent E. A. Colling has started the 10-stamp mill of the Combination M. Co. at Goldfield, using water piped from Alkali Springs, 10 miles northwest of Goldfield. They are milling ore from the Combination and the January.

##### Lincoln County.

The Irish Mountain district, 10 miles from Hiko and 50 miles from Caliente, is attracting attention. L. F. Peer, manager of the Illinois property, reports that the county will pay for repairing the road between camp and Hiko.—T. Hatfield, Vickery, Pike & Smith, W. J. Lawrence and G. Wilson are working different properties in the district.

##### Nye County.

The Silverbow mining district has been formed, 50 miles east of Tonopah and 45 miles northeast of Goldfield. Water and wood are said to be plentiful and a number of prospects are being developed.

#### NEW MEXICO.

##### Grant County.

It is reported that work is to be resumed on the Wild Cat mine, at Santa Rita, which has been closed because of litigation.—C. P. Crawford and R. Worthing are putting in a concentrating plant to treat the dumps around the Chino mine, near Santa Rita.—C. A. Stevens is developing claims at Chloride Flat, near Silver City.

#### OREGON.

##### Baker County.

A 10-stamp mill is to be put up at the Queen of the West mine, in the Cornucopia district.—It is reported that a mill will be built at the Mayflower, near Cornucopia.

Placers are suffering from want of water in many sections of eastern Oregon. Especially is this the case on the smaller streams, where placer mine owners have been waiting for a heavier flow of water than has occurred so far this season. Many have already given up the idea of trying to do anything this season and will wait for better conditions next year. Along the larger streams much work is being done, as miners are not so handicapped by shortage.

A rich strike is reported in the Platts' group, Rock Creek district, possibly on an extension of the Cracker Creek lode. H. T. Hendryx of Sumpter is manager.

##### Douglas County.

Director of the Geological Survey C. D. Walcott has informed the mine owners of the South Myrtle Creek district that the samples of black sand sent to him from their properties contain platinum in paying quantities. A. M. Armitage, who is superintending the Yellow Jewel work on South Myrtle creek, sent the first samples.

##### Grant County.

The dredger at the Crane Flat mine, near Grant, has been started by Burch & Burbridge of Spokane, Wash.

**Jackson County.**

The Sterling mine has been sold by H. E. Ankeny and V. Cook to F. J. Blakely and the Sterling Mine Co. J. D. Heard will be manager.

**Josephine County.**

It is reported that the Takilma smelter is to be blown in on June 1, or as soon as the roads dry up sufficiently. The smelter has a capacity of five tons of matte per day.

The Improved S. & M. Co. of Portland has completed plans for a 50-ton custom smelter in Grant's Pass. J. V. Snowgoose is manager.—J. MacCann of Medford has a bond on W. Febeley's property on Upper Sucker creek.

Superintendent W. I. Fleck of the Lewis & Clarke property, near Grants Pass, intends to put in a small compressor, to be run by water power.

**Lane County.**

(Special Correspondence).—G. Bohlman, who owns five claims in Bohemia, has good returns on assays.—The Champion Basin M. Co. are making preparations to begin work.—W. H. Shane will commence a tunnel on the Pittsburg property at Bohemia.—A. B. Wood, manager of the Oregon Securities property at Bohemia, states that the machinery at this big plant is working well. Twenty of the thirty stamps are dropping. Cottage Grove, May 16.

**SOUTH DAKOTA.****Lawrence County.**

The Imperial M. Co. has completed an addition to its cyanide plant in Deadwood, which will make it possible to treat 4500 tons of ore monthly. The company has nearly completed the payments on the McGovern ground, at Bald mountain. The company is crushing a little coarser than formerly and is allowing a longer time for leaching.—The Richmond-Sitting Bull M. Co. has been organized in New York City to build a cyanide plant to work the low-grade silver ores found in the Sitting Bull and Richmond mines at Galena.

**UTAH.****Juab County.**

Work has been resumed at the Mammoth mine at Eureka.—Ore shipments from Tintic for the week ending May 15 were: Eagle & Blue Bell, 7 carloads; Yankee Con., 4; Bullion-Beck, 8; Gemini, 7; Ajax, 2; Carisa, 2; Grand Central, 4; Mammoth, 1; Victoria, 6; Star Con., 3; May Day, 6; Uncle Sam, 2; Centennial Eureka, 92; Swansea, 1; total, 145 carloads.

**Salt Lake County.**

It is reported that E. A. Wall will enlarge the Amanda tunnel of the Starless group at Bingham and put in an air compressor and power drills. It is stated that the Amanda tunnel has cut the copper-bearing porphyry.—A new air compressor and hoist are being put in at the Butler-Liberal at Bingham.—The name of the Red Wing Extension Co. at Bingham has been changed to Massasoit. Manager McCarrick of the Massasoit is working four men and is drifting from the shaft at a depth of 425 feet, where there is a good showing of galena ore, with some copper.

**Summit County.**

It is reported that work is to be resumed at the Silver King Con. as soon as the Ontario No. 2 hoist can be moved to the Silver King. The shaft is down 800 feet. A new compressor is to be put in. J. McGivern will have charge of work. S. Spiro is manager.

**Utah County.**

The mill of the Utah Ozokerite Co. at Colton has been started on ore from the dump.

**WYOMING.****Natrona County.**

The Cole Creek M. Co., operating the Muddy mines between Douglas and Caspar, is putting in a new hoist, dynamo and boilers. M. E. Kennedy is superintendent.

**FOREIGN.****AFRICA.**

It is reported that the Rand gold industry has reached, so far as output is concerned, the position that it held previous to the Boer war. Recent improvements have been tube mills, power gas plants, and the more extended use of slime plants. It is estimated that the use of tube mills will give a 5% higher extraction at a cost of about half of the value of the extra gold obtained with the high-grade mines. At Cinderella Deep, a power gas plant is being built in expectation of reducing the fuel bill. Many mines are short of native labor and others employing Chinese have not yet had time to bring them to the full degree of efficiency. The miners claim that it is unfair that the mining companies should be compelled to pay a minimum rate of wages of 1 shilling a day, which is increased to 50 shillings a month after the first six months. Under the existing arrangement a Chinese coolie, the mining operators say, can do as small an amount of work as he sees fit, and the company by which he is employed must pay him his stipulated wage whether he has earned it or not. At the Van Ryn, which received one of the earliest batches of Chinese, the working costs have fallen during the past twelve months from 25 shillings 7 pence to 18 shillings 11 pence per ton milled. The reduction is probably mainly due to the increased rate of working, but nevertheless goes to prove that the cost of Chinese labor will not be greatly different from the cost of Kaffir labor.

**CANADA.****BRITISH COLUMBIA.****Boundary District.**

W. S. Macey has men working the Tip Top at Skylock.—M. Bellefontaine and M. McDonnell have struck a good vein of free ore on the Buttercup, 2 miles east of Eholt.

The Hartford group at Hartford Junction, owned by

the Hartford G. M. Co., in which S. H. C. Miner is interested, is to be worked after being idle for five years.

**Cariboo District.**

S. Keast has started boring at Wingdam, Lightning creek, to determine the best method of working the ground. Ashcroft is the nearest railway point.—The Sil-Why-A-Kin Mountain M. Co. has been formed to work the Clearwater mica mines, 60 miles northeast of Quesnell Forks. A. J. Colquhoun is manager and engineer.

**East Kootenay District.**

G. O'Brien, a fire boss at Coal creek, was recently fined \$10 for firing a shot with a naked light.

On May 20 the Sullivan M. Co.'s smelter at Marysville is to be blown in. Crushing in the mill has been going on for some time, and the two mechanical roasters, with a capacity of forty tons per day each, have been started. The Sullivan M. Co. has resumed work at its mine 3 miles from Kimberley. There was a temporary shutdown while an addition was made to the crusher buildings at the smelter. Active work has been resumed at the Dominion group, which expects to ship ore to the smelter after the blowing in.

W. Haupt of Wilmer has started work on the Tecumseh mine at the head of McDonald creek in the Windermere district.

**Nelson District.**

J. N. Scott intends putting in a power drill and 5-stamp mill at the Dundee M. Co.'s property, 6 miles from Nelson.

**Rossland District.**

The Le Roi concentrator has been given a test run in part. Superintendent Mitchell has been putting through the mill small lots of second-class ore, and he says this concentrator will solve the problem of successfully concentrating them. Following are the shipments for the week ending May 13: Le Roi, 2050 tons; Center Star, 1500; War Eagle, 1500; Le Roi No. 2, 90; Le Roi No. 2 (milled), 600; White Bear (milled), 300; Jumbo, 200; Spitzee, 60. Total for the week, 6300; for the year, 128,114 tons.—Following are the figures of the payrolls in detail for April: Le Roi, \$21,000; Center Star, \$19,400; War Eagle, \$12,260; Le Roi No. 2, \$7843; Spitzee, \$2000; Jumbo, \$2000; White Bear, \$2000; smaller mines and properties, \$5000; staffs of mines and mills, \$10,000. Total for mines, \$81,503. The smelters—Trail, \$35,000; Northport, \$11,000. Total for smelters, \$46,000.

**JAPAN.**

C. J. Davidson, in a recent board of trade report, says that the Besshi copper mine is in the Ehime prefecture, in the province of Iyo, to the northwest of the island of Shikoku, one of the four main islands of which Japan is composed. The whole range of mountains in which Besshi is situated is composed of metamorphic crystalline schist, containing quartz, mica, graphite, piemontite, and chlorite schists, as well as small quantities of feldspar and serpentine. Around Hataha a poor quality of asbestos is also found, but only in very small quantities. The copper is found at Besshi in the form of a bed, the outcrop of which is on the southern side of the mountain, about 100 feet from the summit. It runs in a single line through the strata at an average angle of 45°, its width varying from 4 to 5 feet up to 30 feet, the mean width being a little over 8 feet. There are eight levels, and a ninth is in course of construction, but it is not yet ready for work to be carried on in it; the depth of the eighth level from the mouth of the inclined shaft is 1300 feet. The galleries are well timbered and packed throughout and supplied with tram lines. The longest gallery is No. 7, which is 3093 feet long, and the shortest No. 8, which is 2736 feet. The greatest output is from the 6th and 7th levels. The ore is extracted by overhead stopping. An inclined shaft runs from the head of the mine to the 8th level at an angle of 49°, and from this crosscuts are driven to the vein. The ore is hauled to the surface in a cage. When the new wire ropeway comes into use the inclined shaft will be used for lowering the ore from the 1st, 2nd, 3rd and 4th levels to the 8th level for transport by the new adit tunnel to Tonaru; the ore from the other levels will be lowered to the 8th by winzes. Hitherto the water in the mine has been pumped to the 4th level, and has been led off by the adit level. In future it will be conducted to a large well on the 8th level, and from there will find an exit through the new adit tunnel to Tonaru, and onwards down the valley to the sea. The circulation of the air in the mine is promoted by the hotter air of the valley being allowed to enter through the adit tunnel of the 8th level and to escape at the mouth of the inclined shaft, near the summit of the mountain, where the temperature of the atmosphere is considerably lower. The air current is made to traverse the various levels by means of doors and stoppings. For blasting, gun cotton is used almost entirely, though dynamite is also employed, especially where much water exists. Black gunpowder is very rarely used. Hinoki (chamaecyparis obtusa) a kind of fir, is used chiefly as timber in the mine, and large forests of it have been planted yearly for the last sixteen years, those planted sixteen years ago being now fit for use. This system of yearly planting will ensure a plentiful supply of timber, which had at one time become very scarce owing to indiscriminate felling. The crushing and sorting is close to the mouth of the inclined shaft. The plant consists of three large crushers. The ore, on being brought to the surface, is crushed near the mouth of the pit and poured down an inclined chute to the mouth of the 4176-foot tunnel which connects the mine with Kadoishiwara on the northern side of the mountain. This tunnel is lighted by electricity and is supplied with a double line of tramway, the trucks of which are hauled by hullocks. On arriving at Kadoishiwara the ore is transferred to the railway running from that place to Sekigasanjo. From Sekigasanjo the ore is taken down the mountain side by two wire ropeways 1 mile long to Hateba, the terminus of the railway, where it is again transferred into the railway trucks and sent to Niihama to be roasted, smelted and refined. But hereafter all the ore will be sent from the various levels down to the eighth level, 1500 feet from the mouth of the pit. From this level

a new adit tunnel, 6000 feet long, connects with Tonaru, the terminal station of the new wire ropeway, now in course of construction. This tunnel has double lines of tramway, which are to be worked by electricity, and the water from the mine is also to be led away by a conduit along one side of it, being eventually conducted to the sea at Niihama. At Tonaru a new crushing plant is being built, after passing through which the ore will be sent down to the sorting rooms below, and, when sorted, it will be poured through shoots directly into the cars of the wire rope line. The crushing, sorting stations and the terminus of the wire ropeway being thus situated respectively one above the other, the handling of the ore is greatly facilitated. The new Bleichert tramway from Tonaru to Kuroishi will be 3600 meters long, the longest span being 600 meters.

It is claimed that 900 tons of ore can be transported in ten hours, the average speed of the hauling rope being 2.5 feet per second. At Niihama there are also coke works, consisting of sixty brick kilns, each of which can produce 1.5 ton of coke in two days. Twelve new ones are now being built. Only coke is employed in the smelting furnaces, the use of charcoal being restricted to the refining process. All the coke is made from coal brought from the Miike mine in Kiushiu. The old reduction works at Niihama were moved to the new works on the island of Shisakajima, 10 miles north of Niihama, where a much larger plant has been set up, the reason for this transfer being a complaint from the farmers of the district that their crops were injured by the fumes from the works. The roasting is carried on in brick stoves, in rows of two, with a common smoke flue running down the center. They are made of slag bricks. There are 549 such stoves for roasting ore and 126 for roasting regulus, and each has a capacity of thirty tons. Roasting is continued for thirty days. For smelting the ore there are three furnaces, each having a circular metal forehearth. The forehearth was at first made of iron, but it was found that they were very quickly corroded by the action of the salt water, used for cooling in the water jackets, and copper ones were substituted for them. The furnaces are rectangular in shape—16x3.2 feet and 13 feet high—the apertures for inserting the charge being on the 30-foot level. Each furnace has twenty-two blast pipes, fed by five large blowers, driven by a 300 H. P. Corliss engine. The blowers make 250 revolutions per minute and have a capacity of 60 cubic feet of air per revolution; they also supply the blast for the second smelting furnaces. The smelting capacity of the furnaces is 187.5 tons of roasted ore in twenty-four hours, and the ratio of regulus to roasted ore is 20%. The smoke flue is placed over the center of the furnaces and consists of an iron cylinder 15 feet in diameter, lined with fireclay. In the inside of the flue large sheets of metal are suspended from the top and fixed at intervals apart; beneath these discs conical boxes, with sliding apertures at the bottom, are attached to the cylinder. The smoke from the smelting furnaces is loaded with dust, which contains from 3% to 4% copper, and, being intercepted in its passage down the flue by metal discs, is deposited in the conical boxes beneath, from which it is collected and made into a soft paste and baked hard by placing it on the roofs of the roasting stoves, after which it is sent to the smelting furnaces. Refining is carried on by means of two reverberatory furnaces, the capacity of each being about fifteen tons per diem.

**MEXICO.**

The following decision has been issued by the Finance Department: Article 47 of the regulations of March 30, 1905, directs in Section II that the exportation of the precious metals which have been brought into the country for treatment therein must take place through the same person as imported them. The President of the Republic being desirous of affording to the mining industry all possible facilities, and in view of the fact that some metallurgical companies have asked this Department that under the conditions of Article 47 of the regulations permission be allowed for the exportation of the metals through a custom house other than that through which they were imported, has seen fit to grant the request. In consequence it will be lawful to effect the re-exportation through a custom house other than that through which the importation took place, provided that the rules contained in said regulations be observed, and that, moreover, in special cases of re-exportation through a custom house other than that of importation, the following rules be complied with: 1. The accounts referred to in Art. 50 of the regulations of March 30 last will be kept not only in custom houses of entry but also in the general custom houses bureau. The assay certificates mentioned in the same article will be sent in duplicate to the custom house of entry and to the general custom house bureau. When it is desired to effect the exportation through a custom house other than that of entry, the interested party will make a request to that effect to the general custom house bureau in order that it may issue its orders, and when receiving advice of the exportation having taken place, it may charge the account of the interested party with the quantity of precious metals exported and may notify the custom house of the importation in order that it may also charge his account with the same amount.

**Aguaascalientes.**

The tin deposit, 40 miles from Aguaascalientes, being developed by C. Pettich, W. A. Pratt, H. Foster and H. Moran, is producing some tin.

**Chihuahua.**

The Chihuahua Enterprise reports that a smelter is to be built at Tabalopa, 3 miles below Chihuahua. Governor Creel says that a concession has been granted for building three reduction plants, aggregating 1000 tons daily capacity, to the American S. & R. Co. F. C. Woodhurn, agent of the company, is at Chihuahua. The initial capacity of the plant is to be 500 tons daily.

**Sonora.**

(Special Correspondence).—The Mineral Hill Co. Co., with its mines in the San Xavier district, has blown in its furnace and is shipping a carload of matte

daily to the Copper Queen Co. Ore is being taken from five shafts on its mines. Another furnace is soon to be blown in and a third is to follow.—At the El Globo mines near Nacozari bids are being made for the construction of a stamp mill, which will begin operations as soon as built on milling ore on the dumps.  
Nacozari, May 15.

The Red Mountain M. Co. has taken over the Cerro Colorado mines, Diego Moreno, in the Altar district, 75 miles southeast of Santa Ana. G. B. Earnshaw of Nogales is general manager. A mill of 500 tons daily capacity is said to be among the plans of the concern. A pumping plant and 6 miles of pipe line to supply water are to be put in.—A 20-stamp mill is being put in at the Martha mine at El Tiro.—F. Monteverde of Hermosillo has sold to A. H. McKay of Santa Barbara, Cal., the Concordia copper mine, 16 miles east of Hermosillo.

## Personal.

G. A. SCHROEDER, a mining man of Denver, Colo., is in San Francisco, Cal.

J. A. ZWARGEL is superintendent Independence G. M. Co., at Red River, N. M.

S. E. BRETHERTON will be in Denver, Colo., about June 5 on mining business.

C. H. MORRIS is superintendent Charter-Raton M. & C. Co., Breckenridge, Colo.

W. E. JONES is superintendent Lluvia de Cohe mines near Hermosillo, Sonora, Mex.

H. CLERC assumes charge of the assay office at the Copper King mine, Letcher, Cal.

C. WOODCOCK has been elected manager Arizona-Nevada Con. G. M. Co. of Bisbee, Ariz.

C. C. MATTHEWS has resigned as superintendent Oregon Securities mine at Bohemia, Oregon.

CHAS. A. DEOLAN is now field manager for Makeever Bros., with headquarters at Marsh, Idaho.

A. C. CUBILLAS has been appointed Federal mineral agent for the Arizpe district at Cananea, Sonora, Mex.

F. M. MOTT of Oakland, Cal., has been appointed manager Los Cochinos M. Co. at Los Cochinos, Sonora, Mexico.

L. R. BUDROW is manager Tiro G. M. Co., operating the Tiro General mine at Charcas, San Luis Potosi, Mexico.

L. M. KING, of the firm of Simonds & King, has returned to San Francisco, Cal., from a professional trip to Nevada.

W. C. HOWARD, general manager New Comstock mines, has been near Kingman, Ariz., from San Francisco, Cal.

J. E. MORRISON is manager Richfield M. Co., working copper mines near Tuape, in the Ures district of Sonora, Mex.

E. L. SMITH has left Breckenridge, Colo., for Seattle, Wash., where he is building a dredger to be used at Nome, Alaska.

A. H. SEEP, vice-president Mine & Smelter Co., Denver, Colo., has returned there from an extended trip through Cuba and Mexico.

R. G. MULLEN will be general manager and J. Taylor will be superintendent of the smelter to be built at Jarilla, Otero county, N. M.

R. E. POSTLETHWAITE has assumed the superintendency at the Potrero, Cal., works of the Risdon Iron Works, vice R. S. Moore, resigned.

R. C. BERKELEY, Pacific coast manager Minneapolis Steel & Machinery Co., Minneapolis, Minn., has returned to San Francisco, Cal., from an Eastern visit.

JOS. RUSSELL will leave San Francisco May 26 to take charge of a gold and tin placer mine at Lagoon Mountain, 100 miles inland from Nome, Alaska.

T. H. TRACY, manager mining machinery department the Power & Mining Machinery Co., Cudahy, Wis., was in Denver last week on his way West.

H. J. SISTY, manager La Libertad mine at Campana, Sonora, Mex., has returned to the mine from New York and West Virginia and will resume development work.

T. B. CROW of Idaho Springs, Colo., has accepted a position as mill manager and metallurgical engineer of the Colorado-Oregon M. Co. at Bohemia, Or., and will take charge June 1.

## Commercial Paragraphs.

THE Keystone Lubricating Co. of Philadelphia, Pa., have opened an office in New York City, room 205, No. 253 Broadway, with Wm. F. Bilveu in charge.

THE Ahendroth & Root Manufacturing Co., Newburgh, New York, have moved their Chicago office, of which A. F. McIntyre is manager, to their new offices at Monadnock Block. This company manufactures spiral pipe, water tube boilers, etc.

THE S. H. Supply Co., Denver, Colo., are furnishing the Ohio-Mexican M. Co., Mexico, a 48-inch, round, water-jacketed copper matting furnace, forehearth, No. 4 positive pressure blower, slag pots, matte pots, 80 H. P. boiler, 60 H. P. engine and electric outfit for lighting.

ROBERT S. MOORE, for many years superintendent Risdon Iron Works, San Francisco, Cal., and John T.

Scott, former superintendent Union Iron Works, San Francisco, Cal., have bought the long-established National Iron Works, San Francisco, Cal., from Marshutz & Cantrell, and will continue the business, with many improvements, additions and alterations.

THE Chromo Steel Works, of Chrome, N. J., have introduced two slight changes in the shoes and dies for stamp mills made by them. One is a slight horizontal corrugation of the shoe shank, which they claim fixes the shoe more firmly in the bosshead, lessening the liability of a shoe dropping out, when the mill is in operation. The other is a depression made by the hydraulic press in the base of the die. This shallow saucer-shaped depression is about 5 inches diameter and 1 inch deep, equivalent to about six pounds in weight. When the die is worn down the loss of weight is in favor of the buyer, as there is that much less waste material.

OFFICERS of the American Smelting & Refining Co. have issued a statement of recent acquisitions and improvements in this country and Mexico. The American Smelters Securities Co., which will succeed to the business of the Guggenheim Exploration Co., has a capital of \$77,000,000. It will be controlled and managed by the American Smelting & Refining Co. The principal properties claimed to have been taken over by the American Smelters Securities Co. are "the Selby Smelting & Lead Co. at San Francisco, Cal., and the Tacoma Smelting Co. at Tacoma, Wash., and operating lead-copper smelters, to which has recently been added a copper electrolytic refinery and plans for copper rolling mills and wire mills. With these smelting plants has been secured a 25-year contract for the entire output of the Bunker Hill & Sullivan mines." Under the original organization of the American Smelters Exploration Co. there was taken over from the Guggenheim Exploration Co. all of its properties in this country with the exception of the Esperanza gold mines. To these properties have recently been added the Central Smelting Co. of Missouri, which is tributary to the lead smelter of the company at Alton, Ill., having a capacity of 125 tons of pig lead daily. Funds are provided for a copper smelter near Salt Lake City, Utah, now being erected and requiring \$3,000,000 to complete and supply with sufficient working capital. In connection with the development of the mining properties at Velardena, Durango, Mexico, owned by the Securities Co., a lead and copper smelter is being constructed. The funds are also in hand for a copper smelting plant in California which will require an outlay of \$2,500,000. Plans are being drafted for a lead and copper smelter at Chihuahua, Mexico, and for the lead-silver business the patents of the Huntington & Huberlein roaster for the United States and Mexico have been acquired. To care for the output of the smelters now planned the copper refinery at Perth Amboy, N. J., is being enlarged by an increased refining capacity of 72,000,000 pounds per annum.

## Trade Treatises.

Chas C. Moore & Co., 63 First St., San Francisco, Cal., are sending out detailed data sheets regarding the Moore oil engine and descriptive literature thereof.

Catalogue No. 43 of the F. M. Davis Iron Works Co., Denver, Colo., describes in detail the operation of the Ferraris ball mill, which is designed for wet crushing.

Bulletin 505 of the Sprague Electric Co., 527 West Thirty-fourth street, New York City, details the advantages and uses of their flexible steel-armored hose for steam and air transmission.

A neat brochure, "The Blue Book of Air Compressors," from the Ingersoll-Sergeant Drill Co., 26 Cortlandt St., New York City, briefly describes and pictures various types of air compressors.

The Little Jap hammer drill is portrayed and described in Bulletin No. 2001 of the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City. This drill requires no mounting and is to be handled by one man.

"Firing Blasts by Electricity" is the subject of a 32-page booklet giving a detailed illustrated account of a successful device for such work. It is issued by the Aetna Powder Co., Chicago, Ill., and is worth reading.

The Westinghouse Electric & Mfg. Co. of Pittsburgh, Pa., have issued a handsome booklet on "The Westinghouse Companies in the Railway and Industrial Fields." The story of progress made by this company is of absorbing interest.

Water power equipment for low heads is invitingly set forth in an artistic pamphlet from the Wellman-Seaver-Morgan Co. of Cleveland, Ohio. Turbines are described in different settings and examples of successful installations are shown. It contains a complete power table of standard turbines.

The attractive appearance of the seventh edition of the crane catalogue of Pawling & Harnischfeger of Milwaukee, Wis., gives a favorable impression of their recent crane construction. Description and illustration of details of construction precede handsome engravings of typical installations in mines, smelters and manufacturing plants. It is valuable to those interested in the handling of material.

## Obituary.

PATRICK J. SULLIVAN, foreman of the Rarus mine at Butte, Mont., died recently from appendicitis.

JULIUS BAER, a well-known mining engineer, died at Hunters Hot Springs, Mont., May 8, of hemorrhage, after a short illness. He was superintendent of the Conrey Placer M. Co.

## Books Received.

"Preliminary Report on the Geology and Under-ground Water Resources of the Central Great Plains," by N. H. Darton, Professional Paper No. 32 of United States Geological Survey. This comprehensive volume treats of the geography of the Great Plains, geology of the Black Hills region, Bighorn mountains, Laramie range, Hartville uplift, and of eastern Colorado, South Dakota and Nebraska. It includes an exhaustive discussion on the underground water resources and economic geology of the region.

"Gold Dredging," by C. C. Longridge, is an ambitious attempt to present a complete account of the status of this comparatively recent method of gold mining. The author logically treats his subject by showing the evolution of methods of the early crude attempts to the latest improvements in modern dredging. After a brief historical introduction, he describes and discusses the advantages and disadvantages of the dipper, the suction pump, the clam-shell and the bucket dredgers. The construction, equipment and operation of the last are described in detail, devoting considerable space to costs and efficiency. Then follows an excellent discussion on prospecting and valuing ground, capital required, possible fields and dredge regulations. The book is devoted largely to New Zealand practice, and the recent rapid advance in the western half of America seems to be slighted. A book of this kind seems to be necessarily a compilation in order to be complete. Such compilation judiciously exercised is an admirable time saver for the reader. But when the author presents pages of unabbreviated extracts involving needless repetition of the same facts and then merely refers to other books detailing methods of gold saving, a proper balance of the essentials and the non-essentials seems to be lacking. In short, the treatment is somewhat verbose. It is adapted more to the needs of the possible investor, desirous of informing himself on the elements of the subject, than it is to the miner whose library room is limited. The author gives the impression that American dredgers are worked almost entirely by spuds, which is not in accord with recent head line workings in California. The numerous half-tone illustrations form an important and valuable feature of the volume. On the whole, while it is lacking in details of recent American practice, yet it gives a better idea of dredging in general and of New Zealand practice in particular than any book yet received. It is published by the Mining Journal, 46 Queen Victoria street, London, England, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of \$2.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

BEER COOLER.—No. 788,895. May 2, 1905. Richard Fincken, San Francisco, Cal. The object of this invention is to provide a simple device which can be readily attached to and detached from any keg in use and which is so adapted to envelop the faucet with a cooling medium that one cold glass of liquor after another may be drawn from the keg, while at the same time the cooler will not interfere in any way with the ordinary operation of the regular faucet. The device comprises a container adapted to hold a cooling medium means for detachably securing it to the head of the keg, said container having a re-entrant wall portion partially inclosing a space to accommodate a faucet; a hinged closure for said space, and a spring-pressed plate carried by said closure to engage the side of the faucet to exclude air from the latter.

PENCIL.—No. 788,998. May 2, 1905. Albert E. Buckingham, Oakland, Cal. This invention relates to improvements in pencils. It is especially designed for use in that class of pencils in which the movable lead is fitted to a body or holder and is slidable therein, so as to advance from time to time, as required. This device comprises a means for advancing the lead and for holding it at any point of advance. It consists of an outer body having a central channel and a longitudinal slot connecting the channel with the exterior of the body, a cylindrical sleeve surrounding and slidable upon the body, said sleeve having a slot or channel coincident with the slot of the pencil body, an exterior sleeve fitting the first named and having interlocking edges projecting through the slot in the inner sleeve and the pencil body and into the line of channel containing the marking lead.

METHODS OF CLEANING IMPURE AND VISCOUS SOLUTIONS.—No. 789,478. May 9, 1905. Henry P. Baldwin, Puunene, Territory of Hawaii. This invention relates to an improved method for extracting finely divided substances in suspension from liquids of varying densities and pertains particularly to the separation by centrifugal action of the solid saccharine particles from their liquids in the manufacture of sugar. There are certain liquids, especially solutions of sugar, natural juices of sugar cane and sugar beet, which contain in solution, substances that will crystallize, but are restrained from fully doing so by the presence of other substances in solution and in a very finely divided state held in suspension in the said liquids. The object of this invention is to devise a practical, certain and cheap method for handling heavy syrups whereby a complete separation of the liquid and contained solids or matter capable of crystallization may be effected. The method of cleaning an impure and viscous solution, containing objectionable substances of about the same specific gravity as itself, in suspension, in a finely divided state, which method consists in diluting the solution with a fluid until the specific gravity of the dilution, and then centrifuging the dilution whereby the centrifugal force will act upon said objectionable substances against the viscosity of the solution under operation, and thus drive them out.

WINDMILLS.—No. 789,497. May 9, 1905. Alfred C. Johnson, Winters, Cal. This invention relates to improvements in windmills; and it consists in means for positioning the mill with relation to the wind, means for the transmission of power from the wind wheel, and the construction of the wheel, the tower, and intermediate supporting devices. The object of the invention is to provide a wind-propelled wheel so constructed that the most effective exterior portions of the vanes of the wheel are available without the weight of a comparative valueless center. A skeleton tower is also constructed as to allow of a free passage of the air through it, so that the wheel being journaled upon the top of the tower the lower half is exposed to the action of the wind. Means are provided for revolving the wheel and its bearings within the tower and means for transmitting the motion of the wheel to a centrally journaled universally adjustable mechanism through which power may be transmitted to fixed apparatus.

MACHINES FOR SEPARATING AND CLEANING HEMP FIBERS, ETC.—No. 789,504. May 9, 1905. Michael G. McLane, San Francisco, Cal. This invention relates to an improved machine for separating and cleaning the fibers of decorticated or partially decorticated hemp, ramie and like fibrous plants. It consists of a suitable support, an endless carrier mounted on said support, a series of alternately arranged rotary combing devices and tension devices in the path of the material carried, said combing devices turnable in a direction opposite to that of the carrier and having rearwardly curved teeth.

## Latest Market Reports.

SAN FRANCISCO, May 19, 1905.

## METALS.

**SILVER.**—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 57½c, refined (1000 fine); San Francisco, 57½c; Mexican dollars, 47c, San Francisco; 44½c, New York.

**COPPER.**—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15@15.25; Electrolytic, 1 to 3 casks, \$15.12½; Casting, 1 to 3 casks, \$14.75@15.00. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £64 6s 6d spot per ton.

Copper maintains practically an even price. Large exports are expected to be made the latter part of this month, which has had the effect of steadying the market somewhat.

**LEAD.**—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 18s 9d per long ton.

**SPELTZ.**—New York, \$5.60; St. Louis, \$5.70; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

**TIN.**—New York, pig, \$29.75@30.15; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 3½c, 35@37½c. London, £135 10s 0d.

**PLATINUM.**—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

**QUICKSILVER.**—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

**BABBITT METAL.**—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

**SOLDER.**—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

**ZINC.**—Metallic, chemically pure, 50c; dust, 3½c, 10c; sulphate, 1½c, 4c.

**NICKEL.**—New York, 55@60c per lb.; ton lots, 40@47c.

**ALUMINUM.**—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

**ALUMINUM.**—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs. 34c; too lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; too lots and over, 31c, Pittsburgh.

## STRUCTURAL MATERIALS.

**IRON.**—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

**STEEL.**—Bessemer billets, Pittsburg, \$23.00@27.00; open heart billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

**WHITE LEAD.**—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 3c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 4c per lb. above keg price.

**Dry Lead.**—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

**LIME.**—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

**CEMENT.**—Imported, \$2.15@2.65 per bbl.; California,

carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

**NAILS.**—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

**LUMBER.**—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

## GENERAL SUPPLIES.

**ANTIMONY.**—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

**COAL.**—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, loog ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Suonside, \$8.50, long ton.

**POWDER.**—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

**CAPS.**—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

**FUSE.**—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

**CANDLES.**—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

**CHEMICALS.**—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, 2½@2¾c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

**OILS.**—Linseed, boiled, bbl., 60c; cs., 65c; raw, bbl., 58c; cs., 63c; Lucol oil, boiled, bbl., 53c; cs., 58c; raw, bbl., 51c; cs., 56c. Kerosene—Pearl, per gal., 18c; As; tral, 18c; Star, 18c; Extra Star, 21c; Ecocoe, 20c, Elaine, 26c; Water White, in bulk, 11½c; Mineral Seal iron bbls., 18c; wooden bbls., 20c; cs., 24c; Miner; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c,

do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

**BORAX.**—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

**BONE ASH.**—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

**LITHARGE.**—Pure, in 25-lb. bags, 8@9c per lb.

**MOLYBDENUM.**—Best, \$2.75 per lb.

**CHROMIUM.**—90% and over, 80c.

**PHOSPHORUS.**—American, 70c.

**SODIUM.**—Metal, 50c.

**BISMUTH.**—Subnitrate, 2½c.

**URANIUM.**—Oxide, 3½c.

**MERCURY.**—Bichloride, 77c.

**TUNGSTEN.**—Best, 1.25.

**SILVER.**—Chloride, 90c@1.00; citrate, 55c.

**RED LEAD.**—500 lbs. and over at one purchase, 7c; less than 500 lbs., 7½c.

**MANGANESE.**—Black oxide, 2½@4c.

**MAGNESIUM.**—Pure, N. Y., \$1.60.

**FIRE BRICK.**—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

**FIRE CLAY.**—Domestic, 1 ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MAY 9, 1905.

789,350.—TELEPHONE SYSTEM—A. K. Andriano, S. F.  
789,352.—HOLDFAST—T. N. Badger, Oakland, Cal.  
789,649.—ELECTRIC SWITCH—W. J. Bell, Los Angeles, Cal.  
789,251.—SHAVING MACHINE—J. A. Benedict, Portland, Or.  
789,261.—FERRULE—J. Davy, Oakland, Cal.  
789,593.—ASH DUMP—C. Dorrell, Seattle, Wash.  
789,268.—LUBRICATOR—R. J. Elliott, Santa Cruz, Cal.  
789,492.—MOP HEAD—C. P. Fonda, S. F.  
789,658.—HEAD REST—W. F. Hedstrom, Los Angeles, Cal.  
789,608.—AUTOMOBILE—B. E. Hervey, Spokane, Wash.  
789,333.—GAS GOVERNOR—F. C. Hodgkiss, S. F.  
789,152.—WEEDER—A. J. Jakiel, Shaw, Or.  
789,497.—WINDMILL—A. C. Johnson, Winters, Cal.  
789,663.—MOTOR VEHICLE—O. J. Killip, Redlands, Cal.  
789,604.—PUMP—L. Look, Los Angeles, Cal.  
789,618.—LIGHTER—H. H. Lyon, Riverside, Cal.  
789,331.—BAG FASTENER—D. G. McClay, Santa Ana, Cal.  
789,504.—FIBER CLEANER—M. G. McVane, S. F.  
789,677.—FUEL FEEDER—F. N. Spear, Los Angeles, Cal.  
789,678.—FUEL BURNER—F. N. Spear, Los Angeles, Cal.  
789,184.—COFFEE CLEANER—C. H. Stubbs, S. F.  
789,578.—BEVEL SQUARE—M. G. Swan, Upland, Cal.  
789,639.—AWNING—F. Thoms, S. F.  
789,303.—ORE FURNACE—P. A. Wagner, Carrville, Cal.  
789,643.—PAPER HOLDER—R. G. Whitlock, Los Angeles, Cal.

## Dividends.

Buoker Hill & Sullivan M. & C. Co., dividend No. 92 of \$150,000, payable 16th inst.; total paid since Jan. 1, 1905, \$675,000; total to date, \$2,946,000.

## LOUIS STRAUS &amp; COMPANY,

Dealers in Ores and Minerals.  
Purchase and Sell Ores of All Kinds.  
Advances Made on Consignments.  
Rare Minerals a Specialty.  
We Also Act as Selling Agents for Mining Companies.  
Correspondence Solicited.

60 and 62 NEW STREET, : NEW YORK CITY.

# REDFIELD All-Steel Electrically Driven Rock Drill

Can be operated successfully in shafts, stopes or up-raises. It has 50 less pieces than any other electric drill. Motor is all-steel; waterproof; ball-bearing.

Can be detached from drill in a few seconds.  
Weights 100 lbs. Weight of drill 175 lbs.

FULL PARTICULARS CAN BE HAD FROM

J. H. REDFIELD, Mgr.

Redfield Drill & Supply Co.

1735 Blake St.

DENVER, COLO., U. S. A.

We also sell Redfield Hand Power Rock Drills

SEND FOR CATALOGUE.

## ANNUAL MEETING.

The Regular Annual Meeting of the Stockholders of the National Cons. Mining Company will be held at the office of the company, 773 Mission St., San Francisco, California, on MONDAY, the 5th day of June, 1905, at the hour of 8 o'clock P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and the transaction of such other business as may come before the meeting.

GEO. W. FLEISSNER, Secretary.  
Office—773 Mission St., San Francisco, California.

NEXT to an advertisement in the MINING AND SCIENTIFIC PRESS, an up-to-date catalogue comes nearest to representing a faithful salesman.

## FRISBIE Patent Friction Clutches Are Unequaled

for Connecting and Disconnecting Line Shafts, Engines, Water Wheels, or Other Machinery Without Stopping Motive Power.

For Friction Catalogue, Address

THE EASTERN MACHINERY CO.,  
NEW HAVEN, CONN.

To the man who pays the bills

ROBERTSON-THOMPSON INDICATOR

Indicates the progressive plant.

HINE SEPARATOR

Gives dry steam to engine—more power.

"EUREKA" PACKING

Combines all that's good in packing.

SPENCER DAMPER REGULATOR

Saves 5% to 15% fuel, by consuming gases.

JAS. L. ROBERTSON & SONS, 195 Fulton St. NEW YORK

Whole No. 2340.—VOLUME XC.  
Number 21.

SAN FRANCISCO, CAL., SATURDAY, MAY 27, 1905.

THREE DOLLARS PER ANNUM.  
Single Copies, Ten Cents.

## Quartz Mining in the Klondike.

Thus far the gold recovered in the Yukon basin, on both the Canadian and American sides, has been from gravels—the detritus of the rocks ground off by glaciers and ice floes, and to a less extent disintegrated by running water. Nearly the entire country is covered with a deep deposit of gravel, overlaid in most places by a greater or less thickness of moss. In California and Australia the geologic and topo-

produce a small amount of gold by the hydraulic method. Although it is not impossible that extensive and valuable bench deposits may yet be found, no deposit comparing either in extent or in richness with the famous "white channel" of the Klondike has been discovered. In that portion of the Alaska interior lying between Circle, on the Yukon, and Fairbanks, on the Tanana, the mountains rise to

point, therefore, in the Klondike region there are two great classes of mining to be considered, namely, creek mining and bench mining. Outside of these two classes there is no mining in the Klondike of productive importance.

The thick covering of moss and gravel renders

Stripping the Violet Vein, Bonanza Creek, Klondike.

Polishing Steel on the Violet Ledge, Bonanza Creek, Klondike.

graphic conditions favor the placer miner. In other countries, notably in Siberia, Alaska and the Yukon Territory, they are inimical to his success. In Alaska, as a rule, alluvial gold is almost entirely lacking where timber and water are plenty, grades steep, and the ground unfrozen. Where gold is distributed in paying quantity water supply is inade-

heights of from 1500 to 2000 feet above the level of the streams, have rounded tops, and slope to the intervening valleys at angles which do not exceed 20°, and often are not greater than 10°. The streams and valleys are on a gently descending plain, the grade of which does not exceed 3%, except in the upper ½ mile, and frequently is not over

prospecting for quartz difficult and discouraging. and outcrops are few. On the head of Bonanza creek, in the Klondike region, some energetic prospecting has been done for quartz veins in the mica schist, and has resulted in the discovery of a gold-bearing vein. This claim has been named the Violet. Accompanying illustrations and another on page 340

quate, timber is poor or altogether lacking, and the miner must provide grade for his boxes and dump for his tailings by artificial means and meet the formidable condition of solidly frozen alluvium. Bench deposits, where gravel can be moved on natural grade, occur in both the Forty Mile and Rampart districts of interior Alaska, and have been made to

1%. The mountains are referred to by the inhabitants as "domes," and the word fairly well describes them.

In the Klondike recent streams have cut the old Pleistocene channels and have reconcentrated the gold. The gold is about equally distributed in the old and in the new gravels. From the miner's stand-

show the discoverers working in the open cuts and shaft sinking with a windlass. The work is being done during the summer and the surroundings are not unlike those found in mines in the Pacific Coast States. It is evident that this vein outcropped at the surface, as in the engraving there is shown very little detritus covering the vein.

## Expert Mine Valuation.

In the valuation of a mine there are many more things which must be determined than the measurement of ore reserves and their tonnage value. There are considerations which require the mature judgement which comes with broad experience. The novice or the inexperienced young engineer is apt to overlook matters of grave importance, while, perhaps, magnifying other things of minor merit. The ore may, perhaps, possess an element which renders its successful treatment both difficult and expensive, and yet, the assays do not show this mineral to be present in quantities which suggest metallurgical difficulties. The tonnage of ore available, as determined by mine development, may be large and the values may be sufficiently high to suggest good profits on mining and milling operations; still, the presence of this single element may overthrow all calculations as to cost of reduction and percentage of values that may be saved. Take as an instance a well developed mine with a large tonnage of good grade ore in sight. If the ore would readily yield a liberal percentage of its values by amalgamation and concentration, with the possible subsequent treatment of tailings by cyanide, the proposition may offer a substantial inducement to the prospective investor. But let the single element antimony enter in even a small percentage and the saving possible by the well-known processes mentioned is impossible. Extraordinary methods must be employed, such as roasting before amalgamation, or something else may have to be resorted to. Either of these additions to the cost of reduction of the ores may mean the entire elimination of all of the profit that had been contemplated, and the investment of capital in the enterprise becomes at once a hazardous venture.

Very rich ores are often able to bear all the expense of high treatment charges and costly reduction, but such mines are usually held by their owners at a price so high that the investment has little attractiveness for the capitalist. It is the ordinary mine which has a good grade of ore, but which requires experienced, careful and competent management to bring success, that is most frequently on the market.

## Inopportune Expansion.

Every experienced mine manager is aware that the expense of milling ores is less in a large mill than in a small one, within certain limitations. He also usually knows that an increase in capacity in a mill having a given equipment, by means of finer crushing at the breaker, by secondary crushing or by any other means, where no additional expense for plant or power is required, means a decreased direct cost per ton of ore passing through the mill, whether a higher or lower saving of values results. The former case, however, is the most appealing to the ambitious manager, for a big mill sounds well, and an increase in the equipment of the mill sometimes increases the manager's estimate of his own importance and value; but this desire for a large plant occasionally leads to results which end in the undoing of the over-ambitious manager. There are numerous instances where a mine under conservative management has been productive and profitable, but the milling plant has been increased to such an extent that the development of the mine has been found insufficient to keep pace with the demands of the mill for ore. With his big mill completed, the unwise manager finds he must put his entire crew on ore extraction, and the hoisting plant is so busily occupied in handling ore, men and materials that dead work falls behind or is discontinued altogether, and in a few months at most the ore reserves are exhausted, and then comes the inevitable shut-down of the mill to await the result of further development. This is by no means an isolated case, for examples are supplied by every mining State in America, and they are not less abundant abroad. Ultra conservatism is no more deserving of applause than is extreme optimism; for the mine manager may be so slow in adapting newer ideas and making necessary improvements in methods, plant and process that he becomes a back number and is actually losing money at a rate almost equaling the extravagance of his neighbor, the over-sanguine expansionist. One of the essential qualifications of a successful manager

is the ability to see clearly the character and extent of his mine, and to expand his sphere of operations on common sense lines. It is far better to have the mine opened several years ahead of the mill, rather than to have the mill or other reduction works two or three times too large for the mine.

## Engineers' Certificates.

The last Nevada Legislature passed a law requiring hoist and other stationary engineers to pass an examination as to their competency. The applicant must make affidavit that he has had not less than three years' experience in the operation of steam boilers and machinery before the commissioners of the county in which the engineer desires to work can issue a license to him. The object of this law is, of course, to lessen the likelihood of accident in the operation of hoisting engines by incompetent and inexperienced men, but, as wise as this provision of the law may be, it does not guarantee the infallibility of the engineer holding the certificate. Hoisting engineers with many years' experience have become responsible for disasters in most unaccountable ways. One man, who had run hoisting engines for twelve or more years, pulled a dozen men into the headframe of a large California mine several years ago. He made no attempt at explanation further than that he was thinking of something else. Engineers sometimes forget what signal was rung after the skip or cage has been started. When a man is found to be preoccupied in this manner the sooner he is sent to the machine shop (or some other department, where his absent mindedness is not likely to result seriously) the better.

There is a growing tendency to protect the working miner and, aside from the natural disposition of the management to do this, generally wise legislation is about the only way in which it can be accomplished. The miner is usually brave to the point of recklessness, where he has freedom of movement, as is often evidenced in mine workings where danger from caving is imminent, but on a cage, skip or bucket in the shaft he is absolutely helpless, depending wholly upon the engineer, and he realizes this. Those whose duties frequently take them down into mines with the men on the going on or off of a shift have noticed that the miners, usually so light-hearted, free and talkative, when passing up or down the shaft, have little or nothing to say from the time they crowd upon the cage or skip until they have safely reached their destination. This is substantial evidence of their realization of their dependence upon the man at the brakes, and that man should be experienced and reliable.

## Testing Safety Devices.

The State Inspector of Mines for Pennsylvania has issued an order to the effect that all mine managers at once test the safety clutches of cages and skips by detaching the vehicle from the cable and allowing the cage or skip to fall. If the safety clutches are in good working condition and efficient no harm will result, as the cage will be hung up in the shaft by the clutches gripping the guides. If the clutches fail to perform the functions they are supposed to perform the cage will drop to the bottom of the shaft and more or less damage and consequent expense will result. This looks like taking heroic measures, but it is certainly not an unreasonable demand on the part of the inspector, for if the clutches, upon which the men depend for safety in the event of the cable parting, are for ornament only and will not do what is expected of them, they are useless. This order is the outcome of the breaking of three hoisting cables and the death of twenty-seven men, the safety clutches having failed to operate in either case. This example of the Pennsylvania inspector is one which could be followed to advantage by every mine in America where safety clutches are attached to cages and skips.

Where buckets and skips on inclines without safety attachments are in use there is no safeguard for the men riding should the cable break, but where such attachments are provided it should be demanded that they at least be trustworthy, and the clutches should be subjected to a frequent test when the cage and skip is carrying as much weight as it usually does when loaded with men.

THE oil producing companies and owners of the several pipe lines in Texas are, it is said, combined for the purpose of controlling the oil industry of that State. This move is simply along the line of precedent already established in California, Kansas and some other oil producing States.

A MORE recent study of the geology of the Tonopah mining district, Nev., by J. E. Spurr, than that made by him in 1903, and published in Bulletin 225 of the United States Geological Survey under the title, "A Preliminary Report on the Ore Deposits of Tonopah, Nev.," has been made by that distinguished geologist, which has resulted in several modifications of his original ideas as to the vein structure and relative age of some of the more important vein systems of the district. To what extent this change in the theory of the genesis of these deposits and their relative age may affect the legal status of conflicting interests in that camp remains to be seen.

SMELTER fumes from the Highland Boy smelter, Utah, have become particularly vicious of late, judging from a complaint of some farmers living in the same county, who in a suit recently brought against the Highland Boy Copper M. Co. claim that the fumes damaged their barbed wire fence to the extent of \$200. One of the peculiar features of these recent suits lies in the fact that the discovery was not made long since that the fumes were detrimental to barbed wire fences and other property. The great prosperity of Utah is built up on the mining industry, which at this time is flourishing in that State, but a few individuals who own land in the vicinity of the extensive reduction works, which contribute largely to the prosperity of the State, are now able to place obstacles in the way of the successful perpetuation of this flourishing industry, in which millions of dollars are invested and upon which the continued prosperity of the State depends.

## CONCENTRATES.

MANY millmen use tinned screens in the batteries without burning.

ONE POUND of the average Western soft coal is equal to 2½ pounds of dry wood for heating purposes.

THE request for information regarding "faults, sheared zones and breccias" will be found elsewhere herein.

It is generally figured that 1 cubic inch of water, when evaporated under atmospheric pressure, will make 1 cubic foot of steam.

A COLUMN of water 2000 feet high, no matter what the length of the pipe line, will develop a static pressure of 866 pounds per square inch.

THE power obtainable by a given stream of water is, within a small factor, due to friction, directly as the head, but the water is not always applied to the greatest advantage.

CONE pulleys arranged side by side, having the hases reversed, furnish an excellent "variable speed" device. They are often made use of in controlling the speed of concentrators.

THE occurrence of carbonaceous matter in eruptive rock masses may be due to the inclusion of pieces of coal which may be in sedimentary beds through which the eruptive rock has forced its way.

THE symbol for a normal solution is N, and for a one-tenth normal solution  $\frac{N}{10}$ ; a centinormal solution is indicated by the symbol  $\frac{N}{100}$ .

It has been repeatedly stated herein that unpatented mining claims can not be held by simply living on them or visiting them occasionally, but the assessment work must be performed, or the claim becomes subject to relocation.

THE standard of horse power for boilers has been fixed by the American Society of Mechanical Engineers at thirty pounds of water evaporated per hour at a pressure of seventy pounds per square inch from a temperature of 100° F.

A STATION PUMP for mine use is usually designed to remain at some particular level, from which it raises the water to some higher level in the mine or to the surface. Station pumps usually, though not invariably, work horizontally. Sinking pumps are suspended in the shaft and work vertically.

THE cheapest way to handle boulders in a hydraulic mine, where a good head of water is available, is with a derrick operated by water power. Blasting and bulldozing of boulders should be done by a small crew when the greater number of men are absent from the pit.

It is not necessary to explode black powder with detonators. These are only used in exploding nitro and similar high explosives. A train of black powder or the ordinary fuse is all that is needed to communicate fire to black powder.

THE standard sizes of the perforations in mill screens are  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1, 2, 3, 4, 5,  $7\frac{1}{2}$ , 10, 12½, 15, 20, 25, 30, 45 and 50 millimeter and upward, with the gauge of plates used in proportion to the perforations. The fine screens are made of the heaviest metal that can be successfully punched by the needles.

THE cost of trenching and pipe laying in trenches depends on the size of the trench necessary to accommodate the pipe, and the depth to which it is desired to bury it, and also to a great extent on the material through which the trench must be cut; this latter usually varies more or less along any line.

IN mine surveying it is preferable to use steel tapes having a length ordinarily of 100 feet, in preference to the old chain system. The mine plans or maps should be made on a scale which will admit of platting all of the necessary details of the workings. It is customary to adopt a scale of 20 or 40 feet to 1 inch.

CONCRETE may be reinforced with bars of iron or steel—old railroad rails, pieces of old mine or other cables and the like, or, for lighter work, expanded metal. The material chosen should be determined by the class of work to be done. Where floors of concrete are to be laid its durability depends to a great extent upon the character of the foundation made for it.

IN the case where A owns a quartz vein striking N.-S. and B finds a vein striking E.-W. cropping on the same ground (presumably within A's lines, but not stated), B must make a discovery of his vein outside of A's boundaries, and he may then work his "cross lode"

through A's claim, having a right of way through A's vein, but no right to appropriate any of the ore found at the intersection of the veins, as this belongs to A, the prior locator. If B can not make a discovery of the vein outside of A's claim, he will have no grounds upon which to locate a claim.

THE exploders used to fire dynamite, called by miners "giant caps," are nearly all made of the same substance—mercury fulminate in small copper cylinders, closed at one end. The strength of the various caps, X, XX, XXX, etc., is determined by the amount of fulminate placed in each grade of caps. A given quantity of this material has approximately the same explosive force.

MANGANESE DIOXIDE is one of the minerals which usually gives more or less trouble in amalgamating gold ores, either on plates or in pans. Quicklime is the antidote generally employed to correct this. The lime should be added at the breakers in small quantities at a time to insure its more even distribution among the ore. Where cyaniding follows amalgamation the quantity of lime must be gauged, to prevent excessive alkalinity.

PIPES for conveying water, air, or oil when laid on the surface should be provided with occasional expansion points to allow for the range of temperature common to the region where such pipes are laid. Failure to make such provisions may result in serious damage to the line, by reason of the shrinkage and expansion of the line at the variable temperatures to which it is subjected. In some regions the ranges of temperature is as high as 150°.

TO ASCERTAIN approximately the amount of water a pump of given diameter of cylinder will raise at a piston speed of 100 feet per minute, square the diameter and multiply by 4. Thus a pump having a diameter of 6 inches and running with a piston speed of 100 feet per minute will raise  $6 \times 6 \times 4 = 144$  gallons of water per minute. In a single acting or plunger pump the travel of the piston can only be counted in one direction, but in a bucket-plunger or differential pump each movement of the piston is counted.

IN most large concentrating mills, where galena, pyrite, etc., are to be concentrated from a gangue, the equipment consists of rock breakers (jaw or rotary), rolls, etc., trommels, elevators, jigs and some device for finer concentration, such as vanners, tables, or buddles. The plant should be arranged to operate by gravity as far as possible, though where sufficient fall is not obtainable, conveyors of various kinds cheaply elevate the material to further pass by gravity from one stage to another of the process.

AN involute may be described as a curve which rolls upon another curve without sliding. The cam arms of a stamp battery are involutes of the circle described by the hub of the cam. This curve may be drawn by wrapping a string around the hub of the cam and attaching a lead pencil to one end of the string, the other end being held firmly. Then unwind the string, keeping it drawn tightly, and marking with the pencil point the curve thus described by the end of the string.

D. G. DEL PRAT, manager of the Broken Hill Proprietary mine, New South Wales, states in the twenty-first volume of the Transactions A. I. M. E. that in filling the workings of a large iron mine in Spain he used no fines whatever. All the waste employed came from the surface and was placed by hand, and the settling of this filling in a stope 100 feet high did not exceed 1 foot, and usually was not over 6 inches. If fines were also used it is probable that the settling would be as much as 10%.

THE quantity of water discharged through the nozzle of pipe under known head may be approximately determined as follows: Extract the square root of the head in feet and multiply this by 8.03. The product will equal the spouting velocity in feet per second. Multiply the area of the nozzle at the mouth by this velocity and the result equals the cubic feet of water discharged per second. Thus a 6-inch pipe under 400 foot head will discharge  $\sqrt{400} = 20 \times 8.03 = 160.6 \times 28.27 = 4523.8$  cubic feet per second.

THE cost of a dredger depends upon its construction. Dredgers are built for specific work, and a dredger built to operate under one set of conditions may not work to the greatest economical advantage under another set. The important factors to be predetermined when planning a dredger for gold mining are: Depth to bedrock from the level of the water; height of the bank above the water level; depth of water; nature of the gravel or other material to be mined; character of the bedrock—hard or soft, etc.; size and shape of the gold particles to be saved by the machine; cost of transportation from railroad and freight rate from point of building machinery to railroad station nearest the dredger site; cost of lumber delivered on the ground.

SOME geologists believe that the gold veins of Nova Scotia are similar to those of Bendigo, Australia, and the more extensive development of these mines is being conducted along the lines suggested by this belief. The summit of the "saddle" or apex of the anticline is usually the strongest in development of gold-bearing

material, though not always as rich as the ore found in the "legs" of the anticline. The synclinal portions of the series of folds in which these deposits occur are uniformly lower in grade than the anticlines, and sometimes the quartz and gold are entirely lacking in these parts of the formation. The ores are treated by stamp-milling amalgamation and concentration of the sulphides.

MUCH hydraulic cement is being made from blast furnace slags in the United States and it is known by test and experience that, when properly made, the cement thus manufactured is for many purposes as good as Portland cement. Only a slag of proper composition can be used for this purpose. A furnace slag, such as is produced at iron furnaces, having approximately the composition, silica 26%, alumina 16%, lime 55% and magnesia 3%, would probably be suitable for this purpose. The slag must be thoroughly granulated by discharging while hot in an excess of water. Slags allowed to first solidify are not suitable for cement making. The slags from copper and lead furnaces are not suitable for making cement, owing to the large percentage of iron present.

IN California by one barrel of crude oil is meant 42 U. S. gallons, or 9702 cubic inches. Six barrels of oil weigh approximately one ton of 2000 pounds. The drums ordinarily used to transport crude oil contain about 110 gallons of oil, or a little over 2.5 barrels. In speaking of the specific gravity of crude petroleum, the scale of Beaume's hydrometer is referred to, which is used to measure the density of liquids lighter than water. Oil is usually tested for specific gravity when at a temperature of 60° F. For correction it is customary to allow 1° Beaume for each 10° difference in temperature of the oil, above or below 60°. Thus an oil which is 14° B. at 60° F. is calculated to register 13° B. at 50° F.

A FOREHEARTH is placed at a smelting furnace for the purpose of drawing off the molten products as fast as they are formed in the furnace. In the forehearth the metal has a chance to separate from the slag, and both metal or matte and slag may be drawn off separately from the forehearth as desired. The forehearth is lined with clay and silica, something after the manner of a converter. The charge in a forehearth always chills slightly around the edge, thus practically reducing its capacity. At one furnace the experiment was made of building a forehearth of large diameter, but it was found that the material around the edges chilled to a greater extent than before, so that the capacity of the large hearth exceeded that of the small one but little, if any.

THE loss of air between the compressor and the drills may be due to any one or all of several causes. These are leaks in the pipe line; abnormal friction in the pipe line, due to rough pipe, and frequent sharp bends; frost in the pipe line in cold weather and water due to condensation of moisture during moderate weather. Another source of annoyance is the leaving wide open of one of the cocks on a hose which has been detached from a machine after blasting for the purpose of driving out the gases and smoke. This weakens the pressure at every other machine in the mine for the time being, unless the compressor is large enough to easily supply the loss due to this cause. Air pipe lines should be of sufficient diameter to admit an easy flow of air through the pipe and not cause it to travel at a high velocity, thus increasing the friction. It is advisable to use either straight-way or gate valves on air lines, as globe valves cause much loss from friction.

THE theory upon which the "cut hole" idea is based in blasting rocks in place is that a quantity of explosive placed in a hole drilled into the rock will cause the rock to break out a crater or funnel-shaped mass of the rock, the sides of which are supposed to have a slope of 45° to the direction of the drill hole, but this result is only obtained in practice in absolutely homogeneous rock, and not always then. Under ordinary conditions rocks have a certain rift, that is, a tendency to break along certain planes. There are also jointing planes which induce rock to break in various directions other than those calculated theoretically. In placing cut holes in shaft sinking, for instance, if the holes are 8 feet apart at the surface of the rock and directed toward each other at an angle of 45° to the vertical, these holes should meet a common plane of 4 feet below the surface, and the holes would each be about 5.7 feet in depth. When this cut is fired, if it breaks well it is not likely, in hard rock, to break out much back of the line of the drill holes themselves, as the "hurden" on the holes is too great. In many mine workings in very hard rock the fallacy of the "crater" theory is demonstrated where the line of nearly every hole drilled to the limits of the cutting (drift or shaft) is in plain sight. This usually only occurs in very hard ground. Under favorable circumstances, as in some soft sandstone, the breaking of the ground may exceed the calculations of the miners. Miners drilling by hand usually figure much more closely on the effect of each hole drilled than do machine miners, who place holes systematically over the face of drift or bottom of shaft, trusting to over-charge of powder to do the work. Many miners show lack of judgment in the use of high-grade powder, using as large an amount of No. 1 70% nitro powder as they would customarily use of No. 2 40%, though the former has nearly two times the explosive force of the latter

## The Compression of Stope Fillings.\*

Written by B. J. OBERHAUSEN.

In the Ruhr coal district there is a generally accepted saying that when the rooms are filled with waste the amount of setting which takes place does not exceed 40% of the thickness of the seam; and that, as a rule, the settling is much less than this maximum. Up to the present time no definite data relating to the matter have been published. Certain small scale experiments, which were made at shaft No. 2 of the Kaiser mine by means of a brick machine, confirmed in a general way the supposition referred to above. The results of these experiments are given in the table, which shows, for the various materials used for filling, an average compressibility of 32.3% of the volume originally occupied.

The exploitation at the above-mentioned mine has recently furnished facts which lead to more definite

won from rooms which are afterwards completely filled, together with the adjacent development work. The strata overlying the coal formation have an average thickness of 220 m. and consist largely of the younger formations, mainly Upper Cretaceous. The seams being mined are those marked No. 1 and A, B, C, D and G on the accompanying section, and are at an average depth of 370 m. These seams vary in thickness between 1.8 and 0.5 m., averaging 1 m. The regular dip to the northwest usually does not exceed 25°, except in the western portion of the area, where, in the neighborhood of a fault, it reaches 60°. Its average is not over 15°. Between the individual seams the formation consists chiefly of clay slates, sandstone and sandy shales occurring only in three horizons, each 20 m. thick, situated respectively between seams C and D, D and E, E and F (Fig. 1).

The methods of mining employed, which depend on the nature of the seams and various local conditions, are as follows:

(a) Strebau—Long wall working, on strike or dip,

most cases it was quite evident that the settling within the seam itself had ceased. Between the foot and hanging walls the filling was hard and tight, having been even squeezed into fissures and cracks formed in the adjoining country rock. The filling forms a compact, breccia-like mass, and has been re-cemented, especially where granulated slag was used, into a hard material which could be broken only by blasting.

A comparison of the various data obtained shows that in Stossbau and Strebau (defined above), when granulated slag and broken rock were used for filling (seams 1, D and G), and when the drifts and inclines were filled at the same time, the setting was a minimum, averaging not over 25.5% of the original thickness. The settling was observed to be much greater than when, instead of introducing outside rock, the filling was composed of country rock broken in the adjacent development work. Especially is this true when the drifts, self-acting, inclines, etc., were only partially filled (seams A and B). Under these conditions the settling amounted to 38%. In seam C the

Fig. 1.

Fig. 2.

conclusions as to the compressibility of the filling. These data being deemed of general interest are given below:

Character of Filling.	Weight per cubic foot, lbs.	Thickness of Filling, m.	Percentage of Compression, %	Remarks.
White granulated slag.....	0.550	74	39	The space in the press charged with filling was 255 m.m. long, 123 m.m. wide and 74 m.m. deep.
Gray granulated slag.....	0.722	74	42	
Dark gray granulated slag.....	0.858	74	45	The pressure die, weighing 700 k., was dropped a distance of 142 m.m.
Black granulated slag.....	1.201	74	49	
Ground clay slate, up to 5 m.m. in size.....	1.201	74	56	Material to be tested had to be committed before charging the press.
Ground micaceous sandstone.....	1.297	74	59	
Ground sandstone.....	1.317	74	61	
Mason's sand.....	1.250	74	53	
Cinder.....	0.742	74	44	
Coal slack.....	1.021	74	54	

The field of operations of the company lies chiefly in a district frequently flooded by the Rhine and the Ems. This induced the mine management to adopt the plan of filling the workings, in order to reduce to a minimum the surface depressions incidental to mining. In the area tributary to shaft 2, near Marxloh, this system has been carried out in a most complete manner. The daily production of 2200 to 2300 tons is

either with straight face or series of stepped or off-setting faces.

(b) Stossbau—Overhand breastwork, on the strike or to the rise, in horizontal slices, with use of filling.

(c) Stoss-Firstenbau—Overhand breastwork, in steeply dipping seams.

The material which was used for filling comprises: (1) Waste rock broken in mining the coal; (2) waste rock broken in prospecting and development; (3) waste picked out from the run of mine at the surface; (4) granulated slag from neighboring iron works.

For the normal production of 2300 tons per twenty-four hours there are used as filling: Of No. 1, 125 tons (250 loads); of No. 2, 250 tons; of No. 3, 15 to 20 tons, and of No. 4, 200 tons. This filling is conveyed to the working places partly through the airways and partly through the haulage gangways.

During the past year at the Kaiser No. 2 mine, it has been decided that air and haulage ways, which must be maintained for a long period of time, are best run through the old stope fillings. For this reason several considerable portions of the mine, which were worked out some years ago and subsequently filled, were again opened by drifting through them.

The original thickness and composition of the seams was accurately known from former records, which have been carefully kept for each portion of the mine. The thickness of the worked out and filled seams were measured at a number of places during the driving of the new drifts and the resulting averages obtained. Self-acting inclines, raises and airways were driven practically through the middle of the various worked out areas of ground.

The country rock and the filling found in place where penetrated by the various new drifts, and in

rooms were only partially filled to a breadth of 6 m. with waste broken in the drifts. The adjoining drifts, which were 2 m. wide by 1.5 m. high, were originally left opened and have not yet closed completely. Such material as they contain has in part been squeezed into them from the rooms. Here the settling has not ceased, although already amounting to something like 60% of the thickness of the seam, (Fig. 2).

The facts noted show that the compression will average 30% of the original thickness when the workings are completely filled with waste. Observations made in seam C indicate that with partial filling, that is, without introducing outside material to supplement the waste from the mining operations, and without filling the drifts and inclines, the amount of settling will still be materially less than resulting from a system of mining with no filling whatever.

The results first mentioned in the preceding paragraph confirm in a measure the view generally accepted in the Ruhr district concerning the amount of settling which takes place when the rock filling is employed; that is, when the filling is carefully and completely carried out, there need not be more than 30% settling. It is intended to continue these observations, and it is expected that the new system of filling now proposed at the Kaiser mine, in which granulated slag will be used, with water as a transporting agent, will show more favorable results than the old systems still in vogue.

KITCHEN-MIDDENS, referred to in geological writings, are heaps of shells and earth, presumed to be the accumulation of the waste or refuse of feasts held periodically by tribes living upon or near the coast. These mounds are found along the seashore.

\*Translated by C. R. Corning and R. Peele for School of Mines Quarterly, from Glueckauf.

## Shaft Timbering at the Kennedy Mine.

Written for the MINING AND SCIENTIFIC PRESS by  
F. J. GIRARD.

The Kennedy mine, which is located near Jackson, Amador county, California, possesses the distinction of being the deepest mine in the State, ore being removed at the present time from a vertical depth of 2500 feet. Recently 217 feet have been added to the vertical shaft, giving it a depth of 2803 feet, and at present the crosscut to the vein for the 2700-foot level is being run. The shaft is in the hanging wall greenstones, and, being in hard rock and at a great distance from the vein, there has been no trouble from swelling or settling of the ground. There are three equal sized compartments, two being used for hoisting and the third containing the ladders and air pipes.

Before commencing the recent sinking a bulkhead was built across the hoisting compartments below the 2500 chute and the third compartment boarded up, so that the hoisting need not be interrupted during sinking. This bulkhead consisted of three layers of 12 by 12-inch timbers, those of the middle layer being at right angles to those of the other layers. Guides were placed in the third compartment for the

through the upper hanging bolt hole of the plate. After the set had been hung 3-inch blocks were nailed on for bridging blocks and 3-inch planks nailed on all around the set for bridges. Split lagging were used and were placed where needed, close lagging not being necessary owing to the hardness of the rock. Blocks for tightening the set were placed opposite the ends of the wall and end plates and center braces, and wedges of varying thickness were driven between the blocks and the rock. Between the blocks and the bridging boards, or between the blocks and the plates where the ground was too close for bridging, thin wedges (their butts being 1 inch thick) were used. Hard pine was used for the wedges, as the sets would not tighten well if soft wood were used.

For lining the sets two plumb lines were used, one in each of two diagonally opposite corners. Pieces of inch boards were nailed to one of the higher sets and the plumb lines hung over these so that they cleared all the lower sets, the lines being kept suspended from the same points until they had reached a length of 75 or 100 feet. A saw cut for lining was made 14 inches from the inner corner of the set by the framer, and over this the timbermen nailed an inch piece with a saw cut that came opposite the one in the wall plate, the former cut being brought to the plumb line. When no longer needed the inch pieces were removed so the lines could swing clear.

Pine timbers with the following dimensions were used: Wall plates, 16 feet by 12 inches by 12 inches,

## Shear Zones and Breccia.

Written for the MINING AND SCIENTIFIC PRESS.

Shearing in rocks is the result of both pressure and movement. The processes by which shearing takes place are well illustrated in a series of properly chosen rock slides under the polarization microscope. There are two kinds of alteration to which rocks are subjected. These are: (1) Metamorphism, or the passage under conditions of high temperature or pressure, or both, of less crystalline into more crystalline compounds; or the change of minerals into others not less crystalline than themselves. (2) Decomposition, or weathering, that is, the passage under ordinary atmospheric conditions of crystalline rock constituents into compounds less crystalline and more soluble than themselves. Both processes sometimes are in progress in a rock mass at the same time. Rocks may be materially altered by simple pressure, but the strains which are generated within them are relieved and adjusted by the fracturing of the individual mineral constituents of the rock mass and a certain amount of movement along definite planes. These movements produce the condition observed in schists and gneisses. The preliminary process in the creation of schists and zones of shearing in massive rocks is the formation of two or more systems of

crosshead of a bucket that is operated by a small compressed air engine placed in the 2500 station, by means of which all supplies for the shaft were lowered. The waste from the shaft was hoisted in the bucket and automatically dumped into a chute partitioned off from the station ore chute, and thence hoisted to the surface. The men worked in eight-hour shifts, one engineer, two machine men, and two chuck tenders being employed on each shift.

The machine bars were set up, one in each end of the shaft, so that they were 6 inches from the inner sides of the end plates, and all the holes drilled from this one set up. Figs. 1 and 2 show the disposition of the bars and the method of placing the holes. The cut holes were aimed to meet in the middle and were 10 feet deep, the back holes being 8. The entire round was drilled with the machines on the outer sides of the bars. All the holes were blasted at one time and the bottoms blasted until all had broken. An average of 13 feet per week was made.

For the use of the timbermen a stage was suspended by means of four chains which were attached to the hanging bolts above the last set placed, and which hung on the outer side of the wall plates. To the bottoms of the chains were attached iron stirrups, through which passed 4 by 4-inch wooden pieces; on these were placed 16-foot planks, and on these 7-foot planks were laid crosswise to make a tight floor. The stage was removed and the long planks hoisted to the station when a round was fired.

The wall plates were lowered from the 2500 station suspended beneath the bucket by means of a chain and a large clevis, the bolt of which passed

with 6-inch by 12-inch by 11-inch horns; end plates, 7 feet by 12 inches by 12 inches, with 6-inch by 11-inch by 12-inch horns; center plates or dividers, 5 feet 2 inches by 8 inches by 12 inches, with beveled horns 1 inch long, 6 inches at top and 4 inches at bottom; posts, 5 feet 1 inch by 8 inches by 8 inches. Gains 1 inch deep, 6 inches at the top and sloping to 4 inches at the bottom were cut in the inner sides of the plates for the reception of the horns on the center braces, and hanging bolt holes bored 6 and 12 inches, respectively, from the inner set corners. Daps or seats 1/2 inch deep were cut in the plates for the reception of the posts, thus making the posts 5 feet in the clear and the sets 6 feet apart from center to center. The three compartments are each 5 feet by 4 feet 2 1/2 inches. Wooden guides 18 feet by 3 1/4 inches by 4 1/4 inches are used and are mortised together and bolted to the center braces and end plate by means of lag screws, as shown in the sketch (Fig. 3).

Fig. 4 is a sketch of a corner in the Kennedy shaft, showing method of placing blocking, the bridge and wedges. Fig. 5 shows a top and side view of an end plate.

THE copper deposits of Rio Tinto, Spain, were known for many generations, if not for centuries, and were worked in a small way by the Spaniards, but it is only since 1876 that they have been largely productive, under English ownership and management. These mines are the principal producers of copper in Europe, the annual output now reaching about 35,000 tons of metal.

jointing planes in the rock. These planes, if crossing each other at low angles and nearly perpendicular to the surface, greatly facilitate the further process of shearing. When the tremendous pressures to which rocks are often subjected are exerted on a rock mass thus subdivided into flat rhomboidal prisms, the individual mineral crystals are fractured, flattened and drawn apart. These phenomena may be plainly seen with the aid of the microscope. The flattened prisms are drawn out longer and flatter and eventually they are so much distorted by pressure and movement that the original minerals are wholly lost sight of. Augite or hornblende are fractured, flattened and drawn out, and by chemical alterations they pass over into fibrous hornblende, and by further change into scales of chlorite. If the rock is still further altered epidote is likely to appear. Feldspars are altered, passing over into mica and other minerals. Calcite develops as a product of the alteration of the various silicates, and quartz grains are crushed to powder and sometimes are dissolved and redeposited as a cementing material, forming siliceous schists, etc. Zones of rock which have been subjected to this process are described as zones of shearing, and they may be a few feet in width or they may extend over many miles of territory. Slates are often formed in the same manner. Sometimes slates are cleavable along the planes of bedding, but as often they are found to have been subjected to pressure and shearing, as above described, after the formation has been folded. In such event the planes of cleavage and the planes of sedimentation may cross each other at right angles

roads has noticed that when materials in the road are not compacted, there is a constant tendency towards separation by sizes, as the materials have a tendency to work down through the voids and gradually bring the coarse material to the top. In a circular drum the material settles at the lowest point, and when agitated the finer materials work through to the bottom. Each revolution assists at a separation of the material according to sizes. Deflectors are necessary and they scoop up the fine material at the bottom, carry it up and cast it on top so it may again work through. The coarse material is not touched until enough fine stuff has been scooped from the bottom to enable it to settle low enough to be caught by the deflectors. This action is best observed when the mixer is discharging. The mortar comes first and is followed by the stones. When the cylinder is very long the deflectors pocket the fine material and discharge the coarser.

"Concrete in wheelbarrows may look good, but the test of service, or examination in a testing laboratory, shows the difference between cube mixed and deflector mixed concrete.

"A cube revolving on an axis through diagonal corners has the intermediate corners alternately on either side of the center line. The mass is thus thrown bodily from side to side six times in each revolution. As the cube does its best work when

## Reduction of Cinnabar at Sulphur Creek, California.

Written for the MINING AND SCIENTIFIC PRESS.

All those who are familiar with the quicksilver mines of the world are also acquainted with the usual methods of quicksilver reduction from its ores. The ore is mined in the usual manner, the same as the ores of gold, silver, copper, etc., but the reduction of the ores of mercury is distinctive, and throughout the world, wherever quicksilver is mined, the method of the reduction of the ores is carried out on essentially the same lines. The ore is usually divided, by rough screening over grizzlies, into coarse and fine, and these two classes of ore are treated in shaft furnaces by the application of fire, the fire boxes being on the sides of the shaft, but communicating directly with the ore. There is considerable difference in the details of the various furnaces built for treating cinnabar ores, but the principles are essentially the same.

In a few instances, and notably at the Socrates mine, in Sonoma county, Cal., the ore is reduced in a rotary cylinder furnace of the White-Howell type, into which the ore is fed continuously, the furnace revolving very slowly. The vapor is carried into the usual condenser, where the mercury is collected, the

mill, the daily capacity of which varies between 50 and 120 tons, according to the rock. The ore is ground to pass a No. 7 slot screen, which is equivalent to a 30-mesh wire screen. From the mill the pulp is divided (not sized) and sent to two bumping tables, adjusted to secure a coarse concentrate containing usually over 60% cinnabar. The tailings from these bumpers are sent to a second set, which are adjusted to recover the fine cinnabar escaping the first tables. Mr. Northey intends to add more tables, with a view to making a closer saving, if possible, but he has long since realized the difference between saving the last grain of cinnabar as a scientific possibility and saving all that can be saved economically. The concentrates are treated in individual retorts built in a bank of 12. The accompanying illustration shows the character of the retort, with a sectional view of its operation. Formerly this retort consisted of 10 units, 2 having been since added. Sketches of condensers used at the neighboring Boston mine is also shown.

The plant as compared with the usual type of cinnabar reduction works is inexpensive, and possesses the additional advantage of being adapted to a gold mine in case the cinnabar is exhausted and it becomes necessary to close down, while under these circumstances the shaft furnace would be useless.

Some curious, and, as yet, inexplicable phe-

making fifteen revolutions per minute, this means a bodily movement of the mass ninety times each minute. This mass movement is combined with one, which continually subdivides the loose concrete and carries it in thin layers upon each of the six sides. When the surface slope exceeds the angle of repose, the materials fall toward the lowest central point. As the cube is revolving, the falling occurs through the breaking away at the upper edges and a folding over on the lower material. None of the material is carried over by centrifugal force, but all falls in time to be shaken together with the mass as each corner reaches the lowest point. The fine and the coarse material cannot separate but are thoroughly intermixed and the discharged concrete is uniform. In a cube the angles joining the sides are in the line of motion of the material, hence are continually scoured and nothing can lodge. A little water thrown in at the close of the day's work, while the cube is revolving, cleanses it thoroughly. The cube never has to be pounded to keep it clean. It has no insides and has the cleanest discharge of any machine."

This machine is manufactured by the Municipal Engineering & Contracting Co., 607-611 Railway Exchange building, Chicago, Ill.

A LARGE AMOUNT of the copper annually mined is used in the manufacture of brass, the principal foundries and manufacturing establishments being in the Naugatuck valley, Conn. Brass is an alloy of copper and zinc.

smoke escaping through a tall stack.

At the Manzanita mine, in Sulphur creek, in Colusa county, Cal., an innovation in the reduction of quicksilver ores has been in successful operation for some time past. The ore is of the kind usually found in California mines, a metamorphic sandstone, impregnated with cinnabar, iron sulphide and other minerals commonly found in association in the quicksilver mines of the Pacific coast. The ore deposits occur at contact with the serpentine. The sandstone is for most part highly siliceous, and the mine during its early history was worked for gold. As the gold values decreased the cinnabar increased in amount, there always having been more or less of the mercury present in the vein material, until finally the values in quicksilver exceeded those in gold. At this time it was determined by the manager, Geo. V. Northey, who is also now the owner, to attempt to utilize the gold milling plant in the treatment of the ores for quicksilver. This plant consisted of a Gates rock crusher, a 5-foot Huntington mill, and several Gilpin County bumping tables arranged as shown in the accompanying sketch. Almost from the first success attended the efforts of Mr. Northey to concentrate cinnabar from these ores. As carried on at present, the rock from the mine is thrown over a grizzly and the oversize goes to the dump, containing usually too little cinnabar to pay. The ore passing the grizzly goes to the Gates breaker, which crushes it to sizes all smaller than a 1½-inch ring. From the breaker the ore is fed directly to the Huntington

nomina have been observed by Mr. Northey at the Manzanita mine, in the appearance of cinnabar on the faces of rock exposures in old workings where no cinnabar had been known to exist. Pieces of country rock which had fallen from the back of an abandoned drift were found in a few years to be covered with fine crystals of cinnabar, while the rock normally is entirely destitute of the mineral. In one instance a considerable area of rock on the side of an old drift was observed to be covered with an unusual gray efflorescence, such as is often observed on the surface of a damp drift, and which resembles mould in appearance. A careful examination of this material shows it to consist of cinnabar and some other minerals, the nature of which was not ascertained. The only rational theory to which these occurrences can be referred is the probable existence in the mine workings of minute quantities of mercury vapors, and also the presence of sulphuretted hydrogen—in fact, there is no doubt of the presence of the latter—and the formation of mercury sulphide which is precipitated under favorable conditions on the rock faces in the old tunnels and other workings of this mine.

BURRSTONES are made from a hard, siliceous rock, having cellular cavities. This is the typical millstone. Oolitic quartzite is sometimes used for this purpose. Grit is also extensively used for millstones. In fact, any stone which affords a rough surface and is sufficiently hard to wear well is suitable for millstones.

## Mining and Metallurgical Patents.

PATENTS ISSUED MAY 16, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ATTACHMENT FOR DRILLS.—No. 789,703; T. E. Adams, Cleveland, Ohio.

Drill attachment, comprising sleeve to be mounted on column, arm projecting at right angles to sleeve, drill support on arm, bracket on drill support, worm mounted in bracket, segmental gear and clamp for attaching gear to either column or arm and in mesh with worm.

ART OF CONTROLLING FURNACE GASES.—No. 789,844; J. W. Dougherty, Steelton, Pa.

Art of controlling furnace gases, which consists in placing in front of gases emanating from furnace body of inert gas or vapor in sufficient quantity to prevent explosion.

PROCESS OF ROASTING ORES.—No. 789,952; J. A. Anker, J. H. Watson and P. Evans, Los Angeles, Cal.

Process of roasting ore which consists of introducing separate flames into suitable chamber at various points, passing ore through furnace past flames, and alternately accumulating ore in heaps between flames and slowly dumping heaps to gradually deplete heaps and drop ore in several thin streams, respective streams being actively attacked by, and receiving intimate contact with, respective flames; and introducing air blasts into chamber simultaneously at various points to secure same chemical reaction upon all of heaps or streams of ore.

ORE CONCENTRATOR.—No. 790,156; W. M. Reely, Missoula, Mont.

Concentrating apparatus involving reciprocatory and vertically adjustable inclined table provided with series of pans, series of sluiceways arranged at one side of and communicating with pans, pair of sluiceways arranged over table and communicating with plurality of pans at one end of series of pans, combined with means for feeding material to be concentrated to pans independent of plurality of pans, and means for transferring material conveyed by certain of sluiceways of series of sluiceways to the plurality of sluiceways.

SUBMARINE CAISSON AND TUNNEL CONSTRUCTION.—No. 790,046; P. J. Gildea, San Francisco, Cal.

Caisson consisting of concentric arches with interposed air and ballast compartments, means for filling and discharging compartments, edge plates projecting downward from sides of caisson to form close joints with bottom, end gates fitted across caisson, means for hermetically sealing joints thereof, said means comprising flexible bags adapted to receive a fluid under pressure whereby they are expanded against joints, and caisson made capable of receiving air under pressure whereby water is expelled.

HAMMER DRILL.—No. 789,916; A. E. Johnson, Denver, Colo.

In hammer drill, combination with body of instrument and relatively stationary abutment, of hollow crank journaled in abutment at one extremity and connected with body of device at other extremity, and suitable means for introducing operating fluid to crank at its abutment extremity.

APPARATUS FOR BREAKING ROCKS UNDER WATER.—No. 789,981; F. Lobnitz, Renfrew, Scotland.

In rock cutting apparatus combination of cutter, hoisting winch, winding means connecting cutter with winch, sheer legs from which cutter is suspended, clutch on winch, means for operating clutch and device arranged on sheer legs for operating the cutter.

clutch-operating means whenever winding means slacken.

AUTOMATIC DUMPING AND CLOSING BUCKET FOR AERIAL TRAMWAYS.—No. 790,030; E. F. Crawford, Nelson, Canada.

Combination of hanger or pendant, swinging bucket or container mounted eccentrically in hanger, lug carried by bucket, swinging latch mounted upon hanger and provided with shoulder adapted to engage lug to lock bucket in its upright position, and trip disposed in path of latch and having longitudinally extended portion.

ROCK DRILL.—No. 789,951; T. E. Adams, Cleveland, Ohio.

In drill, combination with adjustable support, longitudinally movable drill body mounted on support, and drill operating mechanism carried by drill body, of motor independent of drill body and mounted to rock, rigid drive rod extending from motor to drill operating mechanism, and means for maintaining respective bearings of drive rod in alignment with each other.

METHOD OF RECOVERING COPPER FROM ITS ORES.—No. 790,238; H. M. Wilcox, Chicago, Ill.

Process of recovering copper from its ores by wet way, which consists in leaching ore with suitable reagent to form cupric sulphate solution, blowing air through hot solution to remove iron or other impurities, dosing solution with sulphur dioxide to point of saturation, and thereafter, in closed vessel having proper vacant space left therein, subjecting solution to heat and pressure, suited for precipitation of copper in metallic form while sulphur dioxide is free to escape from liquid into confined space in such vessel provided, to perfect reaction.

## The Cyanide Process.

Written by R. STUART BROWNE.

The following is from "Cyanide Plant Equipment," a trade treatise from the Redwood Manufacturers Co., San Francisco, Cal. In this article Mr. Browne, who is the company's engineer, has given in simple language a description of the cyanide process and attempted to make plain to non-technical readers some points governing the construction of cyanide plants. To those familiar with the process it presents no new features, but to many others it will prove of considerable interest:

The cyanide process is based on the fact that a dilute cyanide solution will dissolve gold in the presence of oxygen. This is explained in the following reaction commonly known as Ellsner's equation:

Briefly stated, the process consists in bringing an ore reduced to a suitable degree of fineness in contact with a cyanide solution; removing the solution from time to time as the gold and silver is dissolved, and replacing it with fresh solution; precipitating the gold and silver from the solution withdrawn; and, finally, subjecting the ore to a wash-water and then discharging it. The gold and silver is obtained in an impure state mixed with base metals, and these are removed by a simple refining process.

The cyanide process is a very flexible one. It may be used for the direct treatment of ores after crushing, or in connection with some other process such as amalgamation, concentration, etc. It is only directly applicable to the treatment of ores in which gold occurs in an extremely fine state of division. Coarse gold will dissolve in cyanide solution, but it may require a very long time to accomplish it. The process is, therefore, necessarily limited to the treatment of such ores as will yield a satisfactory extraction in a reasonable time. Fortunately, coarse gold may be removed by amalgamation, and if, after doing so, the tailings carry sufficient value, the cyanide process may be used for recovering the rest of it, or so much as is practicable.

Sulphide minerals, such as pyrite, yield up their gold to cyanide very slowly, so that when they are of sufficient value it is customary to remove them by concentration, and either treat them separately or ship to a smelter.

A certain class of ores require roasting to make them amenable, particularly those in which tellurides and arsenides occur. As a rule silver ores do not yield a high extraction, but by chloridizing them the silver is converted into a chloride, in which form it readily dissolves in cyanide.

Anything of an acid nature will decompose cyanide. Sulphides have a strong tendency to oxidize and form acid salts. These will react with cyanide and destroy it. It is, therefore, necessary to neutralize them by adding caustic soda or slaked lime to the ore, the amount being determined by means of the acidity test.

The fact that oxygen is necessary in order for the cyanide to dissolve gold has led to a number of patents being taken out for processes in which air or oxidizing compounds are either added or forced into the ore to increase the extraction. It is worthy of note that none of these processes have become very widely adopted, the reason being that if solutions are given sufficient exposure to the air they will absorb enough oxygen for the solution of the gold, and this without the heavy cost entailed by the use of expensive reagents and heavy installations of machinery. However, any method that will cheaply aerate the ore or solution is of great benefit in cyanide work.

We can divide the cyanide process into four operations: (1) Crushing the ore; (2) dissolving the gold and silver; (3) precipitation; (4) refining.

**CRUSHING THE ORE.**—The particular mill to be used for crushing will have to be determined by the character of the ore and the economic conditions. The selection of the proper mesh to crush through is one of the important details. It must be of such size that the gold, after passing through, will have been liberated from its matrix. Fine crushing gives a higher extraction than coarse crushing, but produces more slime. Slime is a product of crushing. It is material reduced to an impalpable powder, and which when wet becomes plastic. It is the most discouraging material that the cyanide operator has to handle, for it forms impervious layers in the tanks and prevents the solutions from passing through.

In dry crushing there is no tendency for the slime and sands to separate, consequently the material going to the leaching tanks, though it may contain considerable slime, will probably be sufficiently porous to percolate. Should, however, the pulp be mixed with a certain amount of water, the particles will be free to rearrange themselves, and will separate out in the order of their specific gravities. If all of the pulp is taken from a wet crushing mill and discharged into a tank the slime and sands will separate and arrange themselves in strata.

Such material cannot be treated. In all wet crushing mills it is, therefore, necessary to put in hydraulic classifiers, and separate the sands and slimes

and treat them separately. The cone classifiers, first introduced in the Black Hills, represent the latest improvement in this line. They are cheap, very simple, and work admirably. The pulp is taken from the plates or concentrators and discharged into the funnel of the classifier. The heavy sands sink down through a rising column of water and flow out at the bottom. The slime is carried up by the current and flows over at the top, and is conveyed to slime treatment tanks or else run to waste.

The sands discharged from the classifiers are taken to the automatic distributors over the leaching tanks. These revolve slowly under the action of the current and spread the sands evenly about the tank. It usually happens that some slime escapes the classifiers and is carried into the tank. To get rid of it, it is necessary to have the tank full of water while it is filling. The slimes are then held in suspension and are carried away by the overflow and caught in a circular launder built around the tank. The latest idea is to drain off the water through the bottom as fast as it runs in and keep the surface of the sands as dry as possible. This makes it possible to mix in some slime without danger of a separation of the two classes of material.

**DISSOLVING THE GOLD AND SILVER.**—A mill treating dry ore or tailings should be arranged differently from one treating wet material. The principal difference is in the arrangement of the pipe system and the sump and solution tanks. In a dry mill there are two solution tanks and the first solution run in is delivered below the filter bottom and allowed to rise up through the ore. A wet mill has no solution tanks, but a double sump system instead, and the solution is pumped on to the surface of the ore and allowed to percolate down. After the tank is filled with ore the cyanide solution is turned in and after becoming saturated it is allowed to stand for several hours and soak.

The precise method of treatment is variable, and the details—such as the strength and quantity of solution to use, the time of contact, and the order of applying the different washes and drawing them off—have to be worked out by experiments. The usual practice is to apply first a strong solution and follow with a weak one of half the strength of the first one; winding up with a water wash, after which the tank is discharged and a fresh charge put in.

**PRECIPITATION.**—The solution withdrawn from the leaching tanks contains the dissolved gold and silver. This may be recovered by any of the following methods: (1) Precipitation on zinc shavings; (2) precipitation by zinc dust; (3) precipitation by charcoal; (4) electrolysis.

Only the first method is used to any extent. It consists in passing the solution through a box filled with zinc shavings. As the solution runs through, the zinc dissolves and the gold and silver are precipitated as a fine powder. Fresh zinc is added once every twenty-four hours. The solution as it comes from the leaching tanks passes to the gold tanks. These are simply storage tanks, and though they are not absolutely necessary, it is convenient to have them. They serve to settle any sands which may have found their way through holes in the filter cloth, and also maintain an even pressure on the solution running through the precipitating boxes. The best way to draw the solution from these tanks is by means of a decantation pipe, or a flexible hose attached to an outlet in the bottom of the tank, and the inlet so fastened to a float that it is kept about an inch under the surface of the solution.

From the gold tanks the solution passes to the precipitating boxes, where, by means of baffle boards, it is caused to flow through the zinc. Here the gold is precipitated. In plants where gold tanks are not used the pipes carry the solution direct from the leaching tanks to the boxes. The solution, freed from its gold, passes to the sumps. In a wet crushing mill the solution is standardized; i. e., brought back to its original strength, in the sumps, and is then pumped back to the leaching tanks. In a dry crushing plant—and by dry crushing plant is meant any plant treating material that was originally dry or nearly dry—the solution passes from the sumps to the solution tanks, which are elevated above the leaching tanks, is standardized here and then comes back to the leaching tanks. All of the solution in the plant is saved and used over and over again. Occasionally the solution may become foul and very weak in cyanide, in which case it may be run to waste.

**REFINING.**—In the United States the precipitate is usually refined by the acid process. The precipitate taken from the zinc boxes contains in addition to the gold and silver, zinc, lead, copper and other metals. This material is put into a tank, and acid, either sulphuric or hydrochloric, is added. The acid treatment is kept up for some time until the base metals are dissolved and the bullion is quite pure. It is then washed with hot water by decantation and then filter-pressed or placed on a filter to get rid of the excess of water. The bullion is then dried in pans, after which the cake is broken up, fluxed, melted down in a crucible, and the bar made ready for shipment.

**THE ARRANGEMENT OF THE PLANT.**—In selecting a site for a cyanide plant it is of greatest importance to choose one with sufficient grade to permit of the

handling of the ore and solution by gravity. This of course is not always possible, so the tanks will have to be raised up on wooden structures. The foundations for these should always be built of concrete or masonry, preferably in the form of long walls. The initial cost of these is much greater than where the wood is used, but they generally prove cheaper in the end. A tank on a weak foundation is apt to move and serious leaks may occur in which the value of the solution lost will greatly exceed the cost of the most substantial masonry work.

If wooden sills are used, care must be taken to see that they are well set and are not placed where they will rot easily.

Cyanide plants may vary greatly in their appearance, but the underlying principles which govern their construction are the same. The leaching tanks are usually large and comparatively shallow. The height depends on the character of the ore. If the material to be leached is sandy and permits the solution to flow through it rapidly, it may be as much as 8 feet, while if it is slimy and retards the flow, it may be only 18 inches. It is not advisable to use tanks with a greater height than 8 feet, for the reason that the ore on the bottom will not yield a high extraction because of the failure of the oxygen to reach it. The tanks are usually made from 5 to 6 feet high and experience has shown that tanks of this size give the best results in both percolation and extraction.

Before ordering leaching tanks the ore should be examined and a tank selected in conformity with its character.

The side of the tank should always be straight, without any batter, and the hoops constructed of round iron, as this form is better able to withstand the corroding action of the cyanide solutions than any other kind. The hoops have only a small surface in contact with the wood, and they dry quickly and may be kept covered with a protective paint.

The number of leaching tanks in the plant depends upon the time of treatment. The time of treatment is reckoned from the time the ore enters the tank until it is sluiced out and the tank is ready for a fresh charge. A sufficient number of tanks should be provided so that one can be discharged every day. If the ore requires a six day's treatment then six tanks should be provided. The capacity of the plant refers to the amount of ore treated every twenty-four hours. If a plant contains six leaching tanks, each of 100 tons capacity, and a tank is discharged and filled each day, then that plant would be a 100-ton plant. If the plant discharged a tank only every day, it would be only a 50-ton mill. Leaching tanks, as well as all other plants used around the plant, should be set up off the ground so that every part of them can be readily examined for leaks. If properly set up on substantial foundations it is not likely that any leaks will occur; but it is best to be on the safe side and not take any chances. It is a good idea to give the tanks a couple of coats of P. & B., or if this is not done, to soak them for a few days with a strong alkaline solution, preferably one containing caustic soda.

The filter bottom is of very simple construction. A grating is laid and either nailed or screwed to the bottom of the tank to prevent it from floating. On top of this is laid either burlap or cocoa matting, and canvas on top of this. The under filter is put in simply as a support. To hold the canvas down on the sides a rope is driven down on top of it between the sides of the tank and the outer ring which encircles the grating.

If the ore is to be sluiced out, one or more discharge gates are put in. Beneath the filter is placed the various pipes with the necessary connections for either admitting or drawing off the solution.

The gold tanks are placed below the leaching tanks so that the solution can run into them by gravity. Sometimes for want of elevation they are dispensed with, but this will necessitate increasing the size of the sumps. Whenever possible they should be installed. These tanks need not be very large. The height is usually 5 or 6 feet. Two tanks are always used—one for weak and one for strong solution. These and all the other tanks should be constructed with vertical sides. They make a stronger and tighter tank than those constructed with a batter, and are much easier to set up. This is an important point in their favor, for in the remote mining districts to which these are shipped skilled labor is usually scarce and costly.

In some plants where the rate of percolation is very slow, montejus or vacuum tanks are used. These are large steel, air-tight drums connected by pipes to the bottom of the leaching tanks. A pump exhausts the air in the vacuum tank and the extra pressure created on the solution in the leaching tank brings on a more rapid percolation. Their action is intermittent. As soon as the vacuum tank is filled it must be emptied, and then the pump has to be started up again and the operation repeated. Gauges are attached to show the pressure within, and the amount of solution. The capacity of a monteju varies from two to four tons of solution. They are not often used, but when they are installed are of great assistance. They are placed above the gold tanks. By using two montejus in series the percolation may be made continuously, one monteju being emptied while the other is filling.

Below the gold tanks comes the precipitating de-

partment. A great many different opinions exist regarding the construction of the precipitating boxes. The ordinary type is a long, narrow box divided into a series of compartments and with baffle boards arranged to force the solution up through the zinc shavings. The dimensions of the compartments vary. The general opinion is that they should be narrow and deep rather than broad and shallow. Most cyanide operators prefer to have the solution flow up through the zinc rather than down. The former arrangement causes a maximum precipitation at the bottom of the compartment which tends to stop up the space under the screen with the precipitate and short zinc. With a down flow this is not so apt to occur. Another point in favor of the down flow is that there is less tendency for the zinc to rise when there is an excessive evolution of gas or during what is known as foaming, when the solution becomes excessively alkaline. With a box arranged for downward flow the progress of the precipitation can be studied better, since it takes place practically at the surface.

(TO BE CONTINUED.)

## Opal Mining in Australia.

Written for the MINING AND SCIENTIFIC PRESS by L. IRWELL, from information supplied by G. C. BERESFORD.

Superstitious associations and evil reputation have for many years prevented a full appreciation of the opal; but that exquisite, vari-colored gem, flashing with living fire, is now beginning to be appreciated as a jewel representing the various emotions of the human heart.

The opal district of New South Wales probably extends from latitude 22° to 32° S., and longitude 140° to 146° E. But the best known parts are situated across the Darling river and between the Bulloo and Paroo rivers in Queensland. Westward, on Cooper's creek, the country is said to be very rich; but as only a few of the most adventurous prospectors have ever been there, the probabilities are that nature will keep her treasures until some inventive genius discovers how to go and take them.

The town of White Cliffs is the center of the New South Wales opal fields, and from it, I believe, nearly all the opals in the world are supplied. The town is a remarkable combination of galvanized iron structures and tents. The former comprise the drinking saloons, the latter the residences of successful miners. The greater part of the population has only the brilliant constellations of the Southern Hemisphere for a roof.

The opal is found in parallel seams at various recognized depths from the surface to 40 feet; but the best gems are obtained on the 1-foot stratum, and, consequently, that level is more exploited than any other. The first operation is to sink a hole about 6 feet deep; then, if no opals have been met with, a rough windlass is erected, and the work of excavation is continued until a seam of opals is cut through or "bottom" (generally the 40-foot level) is reached. If no paying opals have been struck—opals of every color and shade abound everywhere, but those which have not the living fire of green or gold are considered valueless—the miner drives a drift along one of the levels in search of the elusive gem or sinks a shaft elsewhere. But miners are usually reluctant to leave any shaft that they themselves have dug, for they say that one stroke of the pick may lay bare a seam of "pin-fire" or break in two a rich band of "orange." These two varieties of the gem are readily sold to buyers on the field at prices ranging from (in American money) \$75 to \$150 per ounce.

When I visited White Cliffs I had a vague idea that the opal was a blue stone, but I knew nothing whatever of its nature or value or the method of finding it. Having had experience in gold mining, I knew how to secure my claim, and I eventually pegged out one adjoining that of a tall and lean Australian, who said his name was Daniel Crowder and that he had never yet struck a "pot"—that is, a rich find of opals. I labored manfully at my "hole," as Dan called it, and by the end of the first day had excavated 3 feet. On the second day I sent my pick crashing through a substance that rang like glass, and instinctively I knew that I had "struck it" in a double sense. Carefully I worked around the stuff and at length uncovered a layer of deep-blue shining stones which extended away into the side of my shaft. The sun was directly overhead and the temperature about 140°; but I did not feel the heat, for I believed that a fortune was within my grasp. I picked out slab after slab of the glistening stones and burrowed along horizontally. There appeared to be no end to the seam, and before long I had filled my bucket. I noticed that the stones had passed through a series of changes in color, a brilliant pink now taking the place of the former deep-blue tinge. But I did not notice that I was undermining the ground, and I only realized that all was not right when the walls fell in and almost buried me. Luckily, Dan heard my shout, ran to my assistance, and at last dug me out.

"How did you get under that?" he asked in surprise, as I wiped the earth from my eyes and ears. Filled with gratitude on account of my rescue, I answered:

"Dan, I believe there are tons of opals in there. I had filled my bucket and was digging for more when the ground collapsed."

"You filled a bucket?" he gasped.

"Yes."

"Then let me look at it," cried Dan, and, plying his shovel vigorously, in an incredibly short time he had thrown the earth from the fallen wall and had seized the bucket—what we usually call a "pail." Then the air was filled with true Australian bush poetry. When Dan had exhausted his stock of expletives, I asked him to tell me what was wrong. But the look which he gave me in reply instantly sent the temperature in my neighborhood down to zero.

"A bucketful! Tons of it! And I dugged your bucket out! If you weren't such a 'new chum' I'd make you eat the stuff."

"What do you mean, Dan?" I inquired, anxiously. "You haven't explained what's wrong."

"Wrong!" he exclaimed, scornfully. "That stuff's only 'potch,' and the whole lot isn't worth one drink."

"But—"

"Come with me," said he, "and I'll show you tons in my shaft. I'll give you all of it."

To say that I was surprised would be like saying that a temperature of 140° is warm: it is—exceptionally so. When I saw the glistening walls of Dan's shaft scintillating with color right down to the 40-foot level on which he was working, I felt anything but pleased. I soon resumed my labors, however, and kept hard at work for several days. Occasionally I cut through seams of opal matrix carrying stones of beautiful red tints, and others of a curious blend of almost all colors. For all the gems—as I thought that they were—Dan had only one contemptuous name, "potch," which is the miner's name for inferior opals, and, after hearing his verdict, I would go to work again sinking the shaft, my hopes sinking correspondingly.

One day Dan came to me in a fever of excitement, and, sliding down my windlass rope, he soon stood beside me.

"Do you know the nigger's claim?" he asked, abruptly, as soon as he got within earshot of me.

"Yes; it's three claims above mine," I answered.

"What about it?"

"Well," said Dan, "he's 'struck a pot.'"

"Of 'potch,' I suppose. There's plenty of that here."

"Oh, no. Fiery and green flashy stuff, worth £20 (\$100) an ounce, and the seam comes down this way, I think."

"Good luck to the nigger," I said. "If it comes our way, we'll have a chance of striking something better than 'potch.'"

"Yes," remarked Dan; "but don't you see that it may not come this way, and, if it doesn't, we won't stand any chance whatever unless you do the trick."

"What trick, Dan?"

"Can't you get down Black George's shaft, and, with some of your instruments, find out where it goes; and then you and I can go mates, peg out the ground and get down after it."

"Will he let us go down his shaft?" I asked.

"Certainly he will. Come along."

Feeling complimented at Dan's evident faith in my abilities, I went with him, taking in my hand a small spirit-level and a compass. We found Black George tolling at his windlass.

"We hear you've struck it," said Dan.

"You've heard too much, then," answered the dusky one. "I'd just found a few good-colored stones when the seam cut out again."

"It's cut out, has it?" roared Dan. "I think you're lying, because I saw you doing some staking yesterday. Where does it go, anyway?"

"Ah, Dan!" said the negro, with a laugh, "I wish I could find out. It goes somewhere, of course. Come down the shaft."

We at once accepted the invitation and followed him down the rope. Then, after lighting our candles, we crawled into his drive. Our progress was difficult, the drive being irregular and resembling in many respects the burrow of an animal. Dan struggled to find suitable words to express his opinion of George's unmethodical handiwork; but his efforts ceased suddenly, for the drive came to an end at a wall of flashing gems. They sparkled and shone in the candle light—a mass of translucent stones, blazing with that vivid fire that suggests diamonds, rubies and emeralds. I was speechless with astonishment, for it was the grandest display of gems in their natural state that I had ever seen. The seam which carried them, however, suddenly dipped at an acute angle and near the bottom of the wall disappeared entirely.

"Never mind, George," said Dan, as he viewed the apparently "cut-out" seam, "you've got enough opals on the surface there to keep you for the rest of your life."

"Can you make anything out of it?" he continued, addressing me.

"Oh, yes," I replied, using the level. "This seam evidently runs south from here and will probably reappear farther down the hill."

I knew that much from the fact that George had struck the lode at the 30-foot level, while Dan, farther down the hill and directly in the line of the reef, had already sunk his shaft 40 feet without finding any

trace of it. The angle of the dip showed clearly that the valuable opals were far under the workings of our claims; but I knew that, obeying its natural laws, the lode would turn and run up again, like the letter V, and at the same angle.

"It should be near the surface at our lowest boundary peg," I continued, making a mental calculation.

"Is that so?" cried Dan, in surprise.

"It's so," I answered. "I don't know much about opals at present, but I've studied geology a little."

"And does 'gology' tell you that?"

"It does."

"Then I'll shout for 'gology' whenever I see him," was Dan's reply.

"Better let us ascertain if it's correct first," I said, and, taking careful bearings, we ascended George's shaft, and, followed by the astonished negro, we proceeded down the hill.

"About here," I said at length; "the seam should be around this spot; but, of course, it will have turned to 'potch.'"

"Wait till we see," said Dan, smashing energetically at the ground with his pick.

"What was that?" he exclaimed, as a crashing sound followed his first stroke.

"Golly!" ejaculated George. "Let me try, Dan," and, throwing himself on the ground, he tore at the earth with his gouge (a diminutive pick).

Breathlessly we watched him, as with deft hands he threw the stones and gravel aside, and in a few moments there was exposed to our view a layer of opal formation that caused Dan to give vent to some tall words from sheer excitement. The opals were hidden by the white crust of matrix which surrounded them, and might have been mistaken for more of the hateful "potch" but for the piece which Dan's pick had shattered. The broken edges dispelled that idea, as quivering flashes of green and gold shot through its facets and the stone actually seemed to be endowed with life. We looked at each other. The find was a little within my claim, and what it might be worth was as yet a mere matter of guessing.

"My friends," I began, "the probabilities are that this formation extends farther, perhaps towards the west, so that—"

But my audience had gone. They had heard enough; and in fifteen minutes both Dan and George had pegged out new claims in the direct line of the seam, thus abandoning their old claims for the chances that might be in the new. They proved to be right, however, and within a very few days the ground was pegged out for miles around.

The great curse of the opal fields—the curse of most mining camps—is the drinking proclivities of the men; and, although flour and other necessities may sometimes be unobtainable during the dry season, liquor, such as it is, can always be had. To those who care to take it under the circumstances, it may be obtained gratis. Perhaps these somewhat curious circumstances need explanation, for they do not exist outside mining districts. When any man strikes a "pot," he at once sells all that he can easily uncover, and then visits the nearest saloon, where he throws the buyer's check on the bar and shouts for drinks for all comers. (I have never understood why he is in such a hurry or why he makes so much noise.) The news quickly spreads, and soon everybody knows that Sam Hilson has struck it and that free drinks are to be had at the Blue Ribbon, or some other saloon.

In the opal fields there are no labor disputes; every man works for himself. There are no capitalists in the opal-mining business at present. Some miners have a comrade to assist at the windlass, and many strange partnerships are formed for the purpose of working claims. I am sorry to say that miners who never drink more than is good for them are hard to find. The truth is that almost all opal miners have tried other occupations in which they have failed.

The day's work begins at about half-past 8 and is continued more or less industriously until half-past 11. At that time the man at the windlass boils the "billy" (a tin can used as a kettle), and then hauls up his perspiring mate from the candle-light gloom of the workings to the light of day. After eating, mining is resumed till 4 o'clock; but at that hour the opal seeker must cease his daily toil, or he will be forcibly assisted to do so by his indignant neighbors. A hasty meal is usually eaten at 5 o'clock. Saturdays and Sundays are given over to sports, washing—and drinking. Sometimes these days are also taken advantage of to prospect new ground; but, as nobody has yet been able to tell from surface indications what is the formation underneath, the miner often tosses up a coin and determines from its fall where next he will try his luck.

It is curious how the various races of humanity on the opal fields make certain lines of trade peculiarly their own. The camel drivers are all Afghans. The Chinese are well represented among the storekeepers. The bullock drivers are almost of any nationality. The saloon owners are chiefly English or Scotch. The lucky man, as far as successful mining is concerned, is not infrequently an Irishman, and the buyers are all Jews. They often retire from traveling after having made a few trips from Sydney or Melbourne to White Cliffs, and, judging from that fact and their well known characteristics, it is evi-

dent that they do well, even when nobody else does. I have journeyed far and have visited many gold fields in various parts of the world, but I have never visited a gold mining district where a man with no experience may be reasonably confident of at least earning a good living. This may be done on the opal fields of White Cliffs. Almost any man in good health can earn £5 (\$25) per week, and the chance is fairly good for making a small fortune, provided one stays long enough.

White Cliffs, although situated in New South Wales, is much more accessible from Adelaide (South Australia) than from Sydney, and is best reached by rail from the South Australian capital to the town of Broken Hill, and from there by mail coach to the opal fields, a distance of 180 miles. From the other capitals the route is by rail to Cobar, 500 miles west from Sydney. After leaving Cobar, the coach crosses the desert to the Darling river at Wilcannia, and from there another coach runs three times weekly over the remaining 70 miles to White Cliffs.

### Time of Setting of Cement.

The time in which cement will set is variable, and dependent on certain chemical conditions. R. C. Carpenter has given, in the Engineering News, some interesting facts concerning the addition of gypsum and chloride of lime to cement to effect its time of setting. In these experiments the time of initial set was taken in every case as the time when a pat of cement made with a certain percentage of water would bear a rod  $\frac{1}{2}$  inch in diameter carrying a weight of  $\frac{1}{2}$  pound. This method is a common one, but depends to no little extent on the judgment of the operator. It, however, gave results that were sufficiently accurate for purposes of comparison. These tests showed that with an addition of 1% sulphate of lime to the cement the maximum retarding effect was produced, and that beneficial result was obtained by the addition of a larger quantity. In this case, where the percentage of water was 22.1, the initial set commenced in 80 minutes and the final set in 157 minutes.

The cement, without the addition of the sulphate of lime, set very rapidly—the initial set commenced in 2 minutes and final set in 52 minutes. When the percentage sulphate of lime was increased from 1 to 7, the percentage of water being 25.4, the initial set occurred in 18 minutes and the final set in 59 minutes. With other kinds of cement previous experiments had shown that more sulphate of lime than this would have been required to produce the main effect. Other experiments showed that an addition of 2% to 4% of slaked lime to a cement containing a small percentage of sulphate of lime—which latter, through the influence of time, lost its effect in retarding setting—would restore the slow setting properties. Thus, with a cement containing 2% of sulphate of lime, the initial set commenced in 20 minutes and final set in 50 minutes; but with the same cement to which had been added 2% of lime the initial time of set was 6 hours and the final time 10 hours. Cement containing 1% of sulphate of lime, which had partially lost its effect, began to set in 10 minutes and set finally in 20 minutes, while with the same cement with 2% of lime added the initial time of setting was 1 hour and the time of final setting 8 hours.

It is considered that an addition of from 2% to 5% of slaked lime to cement containing sulphate of lime, but in which the latter had lost its effect, will be found useful in retarding the setting of the cement, and that the addition of the lime does not detract from the strength. The addition of slaked lime to cement to which no sulphate of lime has been added does not appear to have any effect on the setting. The investigations of E. Sandlot appear to show that the addition of a feeble solution of chloride of calcium to cement greatly retards the time of setting, but when the solution is concentrated—as, for instance, 100 to 400 grams per liter—it tends to increase the rapidity of setting. Kniskern and Gass of the Sibley laboratory experimented with different percentages of ground chloride of calcium mixed with cement clinker, which mixture they made into parts with just enough water to give the material sufficient consistency, and the results showed that the chloride of calcium was used. On account of the water required 1% of the chloride of calcium would correspond approximately to gauging with a solution of 30 grams per liter in the previous experiments quoted.

As far as the experiments show, it is considered by the author of the article that chloride of calcium added in small quantities has an important effect in extending the setting of Portland cement, and also that it does not have any injurious effect on the permanent strength and hardness. The chloride of calcium can be readily added by mixing it with the water used for gauging. Experiments indicate that the setting can be controlled by the addition of less than  $\frac{1}{2}$ %, which would be something less than 2 pounds to the barrel of cement. Experiments have not been made to show whether the chloride of calcium, if ground with the cement clinker, would have any detrimental effect.

### Mining in the Andes.\*

In the great mountain chain extending from Panama to Cape Horn, and called the Andes, are many great mineral veins and ore bodies. The natives, under the rule of the Incas, developed some of these mines, and Prescott tells of great amounts of gold turned over to the Spanish conquerors by Atahualpa, the unfortunate Inca, to secure his freedom, but which was denied him after the Spaniards had secured the gold. This gold probably came from the placers, as no extensive vein gold mines are mentioned by the chronicler, although silver mines are spoken of. There are gold mines in Panama and in Colombia, in Bolivia, Ecuador, Peru and Chile, and also silver mines, some of them among the most noted in the world. Copper is mined in all of these countries, but more particularly in Chile and Peru. Almost every department in Chile is the scene of copper producing industry. The department of Antofagasta is one of the most important copper producing sections in the world. Tocopilla is just north of Antofagasta, in the extreme northern part of Chile, and is also a copper producer of considerable note. The illustration on the front page gives a view of the port of Tocopilla, with its reduction works, steel piers and other evidences of industry. In the background rises the first range of the Andes mountains, which rise almost from the water's edge to a height of many thousands of feet. There are numerous mines in this front range, some of which are within sight of the city of Tocopilla, though many miles distant. The roads leading upward from the town can be faintly seen in the center and at the left of the picture. On the summit of the first mountain and immediately above the smelting works is the Dos de Mayo mine, and lower down on the slope and just over the outer edge of the pier is the Buena Vista mine. In the big canyon between the ranges at the left is the noted Feliciano mine. Neither of these mines are visible in the engraving, owing to the distance. The accompanying engraving shows the barren appearance of the country in the vicinity of the

I think the Standby and Caledonia mills were duplicates—both knee frame, the line shaft resting on the knees. They were supplied with friction clutches in place of tighteners for starting and stopping the cam shafts. The batteries in the De Smet mill were built in a double row of fifty stamps each, the plates facing each other and the ore bins built over the center of the mill, sloping from the center toward the walls. These bins gave large capacity, but the idea has not since been generally followed. J. F. SMITH.

Liscum, Ariz., May 20.

### THE PROSPECTOR.

The rock samples from Orsco, Or., are: No. 1, diabase; No. 2, diorite aphanite (fine grained diorite); No. 3, a dike rock which is somewhat silicified. Rock of this description is not of uncommon occurrence in mines and in many places forms a valuable ore, when carrying (usually) a large amount of sulphide minerals, pyrite, chalcocopyrite, etc. At such times the rock is usually siliceous. It is of common occurrence in some of the largest California gold mines. No. 4 is diabase porphyrite, but not typical, as the feldspar crystals are too small and indistinct. All of these rocks are often found associated with gold ores, and each of the above samples carry more or less sulphide of iron and copper.

The seven samples from Willcox, Ariz., are all essentially the same—a granular vein quartz, with more or less oxidized iron, copper and lead minerals. No. 1 is granular quartz, with massive and earthy limonite. No. 2 is essentially the same as No. 1, but contains, in addition to the limonite, a little bright red hematite, green copper carbonate and a small amount of lead carbonate. No. 3 is of the same character of vein quartz, but in this specimen the minerals are mostly unaltered, being pyrite, galena,

In the Andes Back of Tocopilla, Chile.

mines. This landscape, compared with that in any one of the mining districts of the State of Nevada, makes the latter look, by comparison, like a land of luxuriant vegetation. In the Chilean picture there is neither tree, grass nor shrub; nothing to greet the eye but the dull redish colors of miles of volcanic rock—andesite. In the left center of the picture the buildings at the Buena Vista mine may be seen, and on the mountain side above are some open workings. The Feliciano property is in the canyon in the center of the picture, but too distant to be seen.

\* See illustration on front page.

### The "A" Frame Battery.

TO THE EDITOR:—I read in the issue of the MINING AND SCIENTIFIC PRESS of April 22 a description of the "A" frame battery and some reference to its having been adopted in the Father De Smet mill at Central City, S. D. I made the drawings of the De Smet mill at Central City in 1878, following the suggestions of the superintendent, A. J. Bowie, and of I. M. West, the contractor, who afterward built the mill. These gentlemen went to San Francisco, Cal., taking the plans with them, and there some of the details of the plans were changed a little, probably at the Union Iron Works, as they made the machinery for the mill. Mr. A. J. Rigby was employed by Mr. West for a time on the mill construction, but he left after a short time to take the superintendency of the Caledonia mine. Mr. Rigby built the Caledonia mill of sixty stamps in 1879, and the Standby mill at Rochford, in Pennington county, also of sixty stamps, and also the hoisting plant at the Pierce mine, in Lead City, south of the Homestake. I worked on the drawings of all these structures with John Rigby, a son of A. J. Rigby, following the suggestions of the elder Rigby.

chalcocopyrite and zincblende. No. 4 shows granular quartz, green and blue copper carbonates, brown iron oxide (limonite), and a little pyrite. In No. 5 the carbonate of lead is more abundant than in any of the other samples. Carbonate of lime is also present as a result of infiltration from outside sources. Copper carbonate is also present in this specimen. No. 6 is about the same as No. 3, and No. 7 does not differ much from the others, but has more iron oxide and less lead carbonate than some of the others. The bright yellow mineral is sulphide, probably of iron and copper, and the color is due to tarnish. Neither gold nor any recognizable silver ore is observed in these specimens, though probably both are present. The rocks should be assayed. In depth the mine should make a good concentrating proposition.

The brown resinous mineral from Deep Creek, Utah, marked "F. L. W.," is garnet rock. The white crystallized mineral is calcite, which occurs abundantly throughout the specimens, being intermingled with the garnet in fine crystals.

The rock from Hayfork, Cal., is a granular quartz rock, stained red by iron oxide, and carrying patches of the black oxide of manganese.

The mineral sample from Bullfrog district, Nev., is chiefly chrysocolla (light bluish green) a silicate of copper. Some quartz is also seen in the specimens, and free gold is abundant. There is also present a few small yellowish scales which are probably embolite (chloro-bromide of silver).

The small crystals from Coffee, Trinity county, Cal., are quartz crystals and of no value, except as interesting specimens.

## Determination of Copper, Arsenic and Antimony in Lead Bullion.\*

Written by H. C. PARMELEE.

The methods set forth in the present paper involve no new points in analysis, but represent the adaptation of well known reactions, to meet special conditions. It is the custom of some lead smelters to require the determination of copper, arsenic and antimony on a sample of bullion representing the monthly output. This may be conveniently carried out as follows:

**SAMPLING.**—As the bullion is loaded for shipment, each bar is sampled in several places with a punch. These punched samples are subsequently remelted and cast into a bar about  $4 \times 12 \times \frac{1}{2}$  inches, this bar representing the carload. Samples weighing somewhat more than 1 A. T. are now punched from the bar for assay, and the clippings which the assayer discards in trimming his sample to weigh 1 A. T. are reserved. Finally the month's accumulation of these clippings is again melted, cast into a bar, and punch-sampled for the analysis. A thoroughly representative sample is thus obtained.

**THE ANALYSIS.**—Treat 10 g. of the sample in a No. 3 beaker with 50 c.c. dilute nitric acid (1-4). Dissolve the lead at a gentle heat and then evaporate down to incipient crystallization. Add 25 c.c. hot water, boil and filter while hot to avoid the crystallizing of any lead salt on the filter.

**RESIDUE.**—The substance on the filter contains almost all the antimony as insoluble oxides. Transfer this to a beaker with about 10 c.c. water. Add 2 c.c. HCl and 1 c.c. HNO<sub>3</sub>, and heat gently until the antimony is dissolved. Then filter through the original paper—wash thoroughly with hot water and evaporate to dryness, avoiding a temperature much in excess of 100° C. Redissolve with a solution of tartaric acid (1 g. in 10 c.c.) and a few drops of HCl. Boil and add to the original solution as indicated below.

**SOLUTION.**—This contains the copper, arsenic and traces of antimony, and should not amount to over 150 c.c. Add HCl in quantity calculated to precipitate the silver present, and sufficient H<sub>2</sub>SO<sub>4</sub> to precipitate the lead. Add immediately and with rapid stirring 50 c.c. alcohol. This will facilitate the rapid and compact settling of the precipitates which should be allowed to stand three hours. Filter under pressure on a Hirsch funnel or a Witte plate—decanting carefully. Wash by decantation three times with a solution of alcohol and HCl (4-1), finally throwing the entire precipitate on the filter and pumping dry. Boil the alcohol from the solution—reducing the volume to about 100 or 125 c.c.—and at this point add the solution of antimony as obtained above. Neutralize carefully with ammonia, add 2 c.c. HCl, bring the solution to boiling and pass H<sub>2</sub>S gas through the hot solution for forty-five minutes.

Filter off the sulphides and after washing transfer to the beaker, using the smallest possible quantity of water. Add 10 c.c. (2g.) KOH solution and heat until the arsenic and antimony are dissolved. Filter through the original paper and wash carefully, keeping the filtrate to about 40 c.c.

To the solution—containing the arsenic and antimony—add 1 g. KClO<sub>3</sub> and 50 c.c. HCl. Boil clear and filter. Make the filtrate ammoniacal, add about one-third of its volume of ammonia, and precipitate the arsenic with magnesia mixture. The arsenic is then determined in the usual manner.

The filtrate from the arsenic is boiled to expel the excess of ammonia, when a large excess (25 c.c.) HCl is added. Cool the solution, add an excess of KI and titrate the liberated iodine with sodium thiosulphate solution. If the same titrating solution is used as for the determination of copper by the iodide method, the calculation may be made on the basis of 126 Cu = 120 Sb.

Copper is determined in the residue insoluble in KOH solution, by oxidizing with HNO<sub>3</sub> and proceeding by the iodide method.

**CONCLUSIONS.**—Among the advantages which the foregoing offers, may be mentioned the ease with which a large bulk of lead is gotten rid of, the separation of practically all the antimony in the first operation, thus avoiding the possibility of retaining it in the lead precipitate, and the determination of all three elements on the same sample.

In the discussion which followed L. B. Skinner said: "In neutralizing by ammonia I think that the point should be brought out strongly that to neutralize the effects of the nitric acid on the subsequent hydrogen sulphide separation, the solution should be made quite strongly alkaline and boiled for several minutes."

"In the subiodide determination for copper this point is brought out by A. H. Low, i. e., that a boiling is necessary for some little time, and in a concentrated solution, to thoroughly neutralize the nitric acid, a mere neutralization with ammonia followed immediately by acidification not being thorough enough. The reason for this probably is that the metallic nitrates are not readily split up with other metals as well as copper. Regarding the leaching of

Windlassing on the Violet, Bonanza Creek, Klondike. (See Front Page.)

the sulphides (precipitated in an acid solution) by KOH I think the point should be brought out that this leach will dissolve some of the lead sulphide and a very small amount of the copper sulphide and the subsequent separations in this solution will be affected if the routine followed by Mr. Parmelee is adhered to, although the use of KOH is preferable to that of NaOH or the sulphides of ammonia, soda or potash, as its solvent action on the lead and copper sulphides is the least of any of the reagents mentioned.

"I have found that the amount of the KOH used should be held closely to the amount necessary to dissolve the arsenic and antimony sulphides, and I am of the opinion that the use of two grams is far in excess of the amount necessary for the arsenic and antimony content in the average lead bullion."

"Mr. Parmelee states: 'Add 10 c.c. (2 g.) KOH solution and heat until the arsenic and antimony are dissolved.' I would like to have him state how he determines the point at which heating is to stop. Or, what is his experience as to the length of time necessary to make a thorough leach?"

"I would like to ask if a precipitate is not formed upon the addition of ammonia before adding the magnesia mixture? In my experience there will be a gelatinous precipitate from impurities in the KOH itself and a precipitate of the lead which has been dissolved. Privately Mr. Parmelee advises that he always has found one and filtered it away. In the article the addition of the magnesia mixture is made directly after adding the ammonia without any intervening filtration. I have found that the lead here precipitated by ammonia or any iron that may have gotten into the KOH solution (and usually the ammonia precipitate shows some traces at least) carries down arseniates and antimonates. Now if this ppt. is not filtered away the magnesia precipitate is contaminated, and, if it is filtered away, it must be re-treated to recover arsenic and antimony. Regarding the determination of the copper in the residue, such a determination will not be total in case the KOH leach has dissolved appreciable quantities."

Mr. Parmelee replied that "the suggestions made by Mr. Skinner from his experience will no doubt add materially to the value of the scheme suggested, and it would probably be advantageous to incorporate them in the method. He has brought up a few points which had not occurred to me to investigate, but which at the same time can scarcely have any great effect on the commercial determination of the metals under consideration. The point regarding boiling with ammonia in order to thoroughly neutralize the nitric acid is acceptable. Referring to the leaching of the sulphides with KOH, it is possible that small quantities of copper may be dissolved, and it is certain that small quantities of lead are dissolved; but the question may well arise whether the copper dissolved by this solvent is sufficient to be estimated by the methods in common use. If not, and I believe not, then this error is one of the theoretical errors which are accepted in commercial work and not considered objectionable. The lead dissolved by KOH at this point will appear when the solution is made ammoniacal previous to adding the magnesia mixture for precipitation of the arsenic. It must here be filtered off, although I neglected to so state in the first paper. Here again the question will arise as to whether the quantities of arsenic and antimony carried down by the lead precipitate will be such as could be estimated by the usual methods or by Mr. Skinner's method. The lead precipitate is extremely small, and indeed will not always appear immediately on the addition of the ammonia, but only after five or ten minutes. Such a small precipitate would probably carry down only infinitesimal quantities of other metals. Regarding the time requisite for leaching the arsenic and antimony with KOH, will say that the appearance of the mixture is the first guide. There should be no indication of anything save a black precipitate and this should be boiled so that the KOH will thoroughly disintegrate

it. I can not state any exact time required, as the leaching was allowed a shorter or longer time according as other work permitted. After bringing the solution to a boil, however, it was usually allowed to stand on a warm part of the bath for thirty or forty minutes."

## Multiple Rider Carrier.

The accompanying illustration shows the multiple rider carrier for button balances, just placed on the market by William Ainsworth & Sons of Denver, Colo.

The weights or riders are each carried by an individual arm and should not become displaced except through gross carelessness. The arms are numbered on their front surfaces to correspond with the weight of the rider carried, and pivoted at the rear to swing clear of the comb-shaped bar below the stirrup. They are operated by a single rod with a thumb piece on the end of it extending through the case. When the arms are up, the riders are carried by them far enough above the comb-shaped bar to not interfere with the oscillations of the beam. In operating, the rod is moved to the right or left until the figure corresponding to the weight of the rider to be shifted stands opposite to the index pointer shown to the left of the frame carrying the arms; then given a slight turn and the arm carrying the rider is swung downward shifting it onto the comb-shaped bar. When the weighing is completed a glance at the figures on the arms that are down shows the combined weight of the riders on the bar. A slight turn of the rod resets all of the riders simultaneously. The manufacturers say that this carrier can be operated with speed and certainty, and the riders can be used for an indefinite length of time without perceptible change in weight.

**RAISING WATER** by means of the hydraulic ejector is not a new idea, for it has been in practical use for many years at a number of places. The largest installation of the kind is that at the C. & C. shaft on the Comstock Lode, Virginia City, Nev. There a plant of this character was installed in 1899 to unwater the Consolidated Virginia and neighboring mines below the level of the Sutro tunnel. At the time of this installation the only cheaply available power was a stream of water under 400-foot head at the collar of the shaft, which at the Sutro tunnel level was something more than 2000 feet. The elevator was a success from the start, but many changes in details were necessary before the plant operated satisfactorily. The water was lowered until a point considerably below the 2150 level of the California mine was reached, when a large plant of electrically driven pumps was put in at that level, and the ejector continued to drain deeper levels, it having now unwatered this and the neighboring mines below the 2350 level. At other places this method has worked satisfactorily and was installed by men of small means and little mechanical skill of a technical sort. In one instance a small stream was utilized under 600-foot head to raise water from a shaft 90 feet in depth. In this instance 9 inches of water were required to raise 3 inches from the shaft; that is, 9 inches were sent into the mine under this pressure to raise a total of 12 inches of water.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Although detailed statistics for the production of gold during the last year are not yet available, preliminary estimates of the production of each State and Territory show that the production of gold in the United States during 1904 amounted to \$84,551,300. After a period of very rapid advance in the gold production from 1892 to 1900, inclusive, during which an increase from \$33,000,000 to \$79,000,000 took place, there were two years of nearly stationary output and one year of decided decrease. It is, therefore, satisfactory to find that the production of the yellow metal has risen again to record figures, the estimate being \$84,551,300, against \$73,591,700 for 1903. Lindgren finds that the sources of this increase are easily traceable. In the first place, Cripple Creek, the greatest gold mining camp of the United States, has gained about \$3,000,000, due to renewed mining activity following the successful completion of a new drainage tunnel, the cessation of the strike which interfered with the production of 1903, and new discoveries of rich ore bodies. In the second place, Goldfield, Nev., during the first year of its existence, added at least \$1,500,000 to the value of the output of that State. In the third place, the production of California has risen nearly \$3,000,000 compared with the production of 1903. This increase is due in considerable degree to the development of the dredging industry in the Sacramento valley. Lastly, the smelting of auriferous copper ores has received a great impetus in Utah, augmenting the gold output in that State by \$1,000,000. These four factors, together with the moderate gains in the production of Alaska, Montana and South Dakota, are sufficient to account for the increase of nearly \$11,000,000 in the production of the last year compared with that of 1903. Lindgren classifies the gold production according to its derivation from placers, dry or quartzose ores, copper ores and lead ores. He estimates the production of gold from placers as \$12,000,000, from quartzose gold and silver ores at \$62,754,000, from copper ores at \$4,300,000 and from lead ores at \$4,600,000, making a total production of \$84,551,000—a sum that practically agrees with the estimate of the Director of the Mint. Alaska is the largest producer of placer gold and should show a gain of at least \$200,000, the output being estimated at \$5,800,000. California will show an increase which may reach \$800,000, the production being estimated at \$4,800,000. This is partly due to a favorable season for hydraulic mining, but chiefly to the great development of the dredging industry. Unexpectedly large areas in Yuba, Sutter, Nevada, Butte and Sacramento counties have proved suitable for the dredging process, while the dredging machines have been greatly improved and enlarged and the expenses correspondingly reduced. At the same time the output due to drift mining and hydraulic mining is on the whole slowly decreasing. Idaho, Montana, Colorado and Oregon have probably maintained their production at the value reached for a great number of years. During 1903 these States, respectively, yielded \$750,000, \$482,000, \$400,000 and \$207,000. Since 1902 New Mexico has contributed over \$100,000 annually in placer gold, derived from veins of unknown age and obtained by dredging operations in Colfax county, but none among the other States has exceeded \$100,000 in output. The production of gold from quartzose gold and silver ores is subdivided by Lindgren into the production of pre-Cambrian quartz veins, \$5,454,000; of Mesozoic quartz veins in the Pacific coast belt, \$21,600,000; and of Tertiary gold quartz veins in the Rocky mountains and Great Basin, \$35,700,000, making a total of \$62,754,000. Auriferous quartz veins of pre-Cambrian age are, so far as known, confined to the Atlantic States, South Dakota and Wyoming. The bulk of the yield from the Atlantic States comes from North Carolina, South Carolina and Georgia and is derived from gold-bearing pyrites. In South Dakota the great low-grade deposit of the Homestake mine is considered to be of pre-Cambrian age. The small production of Wyoming should probably also be credited to the same class of deposits. Auriferous copper ores occur throughout the United States in deposits of widely differing age and form. Some of the greatest copper deposits, however, such as those of Arizona and Michigan, are practically free from gold. The gold from California's copper deposits is estimated at \$272,000 and from Montana's copper ores at approximately \$1,100,000. The mining of auriferous copper ores in Oregon has received a great impetus during recent years, and the production of gold from this source has steadily increased. It is estimated at \$2,100,000 for 1904, but this includes some of the smelting ores from Tintic, which are apt to contain both copper and lead. The gold from copper ores in Colorado is difficult to estimate, as no exact statistics are available, but it probably does not amount to \$500,000. From Colorado and Utah come the principal gold-bearing lead ores. Colorado contributes about \$4,000,000 of gold from its lead ores, one-fourth of which is derived from the Leadville mines. Utah gains about \$400,000 of gold from lead ores, nearly the entire amount of which is obtained from the Park City silver-lead veins.

The general conditions of copper mining in the United States are discussed in a recent bulletin of the United States Geological Survey. The United States supplies about 60% of the entire copper product of the world. The value of the output of copper for 1904, which is estimated at \$95,000,000, exceeds that of gold and is surpassed only by that of coal and iron. Of this production about two-thirds was exported in 1904. Our imports are practically all from Mexico and Canada. The profit of copper mining is shown by the fact that seventeen copper companies declared dividends during 1904 that aggregated \$26,161,000. This is indeed a favorable showing when compared with the dividends of the seventy-seven gold, silver and lead companies, including the smelting trust, which amounted in all to \$19,106,000. It is estimated that the production for 1904 exceeded that

of 1903 by about 8.6%, amounting approximately to 783,000,000 pounds. This increase is due mainly to Arizona mines, but the tremendous development in Utah, notably at Bingham and in the Frisco district, indicates that this State will soon take a more prominent place as a copper producer. When carefully studied, the figures show that the Lake Superior district maintains its relative part of the average increase in the production and consumption of copper, that the same is true of the Montana mines, and that the Arizona mines will show a still greater increase and are likely in the near future to take the lead in the world's production. At the present time the Boston and Montana mines of Butte are the greatest producers in the world. After them in productiveness come the Anaconda, Lake Superior and Rio Tinto mines, named in the order of their importance. The copper deposits of the United States are remarkable not only for their size and productiveness, but also for the variety of their ores. The important copper deposits of other countries consist of chalcopryite, while in the United States ores of this character form a relatively small part of the total output. In a general way each of the great copper producing districts of the country is distinguished by a characteristic ore. In Michigan it is native copper; in Montana, chalcocite or enargite; in Arizona it is largely copper oxides and carbonates; in Tennessee and California, chalcopryite; in Colorado, tetrahedrite.

### ALASKA.

A recent publication of the United States Geological Survey in describing the Ketchikan mining district says that copper appears to be the most important metal of this district, gold and silver being next in consequence. The copper is confined chiefly to Prince of Wales island, which forms the western half of the Ketchikan district. The bedrocks of the island are argillites and white limestones, associated with greenstones. As the result of metamorphism the limestones have been changed to marble, the greenstones to schists, and the argillites to crystalline schists and graphitic shales. Intruding these older strata are masses of quartz-diorite occurring as stocks miles in width, together with dikes and small areas composed of a more basic rock. On the east side of the island from Chomondeley sound northward, including Kasaan peninsula and the west side of Cleveland peninsula, the Kasaan greenstone forms the country rock. Niblack harbor forms an indentation in the shore of Prince of Wales island, and is 36 miles by water from Ketchikan. The mountains rise with steep ascent from the water's edge to peaks 2000 to 3000 feet in elevation. Greenstone is the country rock in the vicinity of the mines, but this, in places, has been altered to sericite, chlorite and amphibole-schists. The ore bodies occur both as small and irregular veins and as mineralized zones. Though the veins are rich in values they will never be of as great importance as the extensive mineralized zones. Chalcopryite, with pyrite and pyrrhotite, carrying gold values, are the principal ores. Developments during the past two years have been confined to ore bodies exposed on the Judge claim, at the head of Niblack anchorage. On the original locations of the Lookout group, situated at an elevation of 1500 feet, on the south slope of Niblack anchorage, only the annual assessment work is being done. The deposits at the Judge claim are large lenticular masses from 10 to 100 feet in width and 100 to several hundred feet in length and depth. These are separated by unmineralized belts of greenstone-schist. The ore—essentially a massive sulphide of pyrite and chalcopryite—occurs in a matrix of altered greenstone, and appears to fill sheared zones, as both masses and fragments of the greenstone occur, completely surrounded by the mineral. Small veinlets of sulphide, associated with quartz, occur in parts of the workings and form what is locally termed a Jasper ore. The developments at Niblack anchorage consist of an inclined shaft 180 feet deep and, leading from this at three different levels, 660 feet of drifting and crosscutting. The ore is said to carry 5% copper and \$1.50 to \$2 in gold values. Concentration of this ore would not be practicable, owing to its massive state and the high percentage of valueless iron pyrite, which can not be separated from it except by smelting or some process of solution and reprecipitation. The mine is favorably situated and the ore from the shaft may be transported in cars to scows or barges for shipment to the smelters. A water power at the head of the anchorage is controlled by the company and can be used to develop enough electric power for mining purposes. On the northeast side of Kasaan peninsula seven claims of the Brown Alaska Co. are extensively developed. The country rock near Hadley, as well as of the greater part of the peninsula, is composed of the Kasaan greenstone with occasional intervening beds of much wrinkled limestone altered to marble. Interstratified in the limestones are beds of magnetite, often carrying chalcopryite. Dikes of felsite and more basic rocks are intruded into both the greenstone and the sedimentary beds. The general trend of the sedimentaries is north-south, and the dip is to the west. The deposits form irregular lenses, generally concordant with the dip and strike of the formations, and seven such masses have thus far been discovered, varying from 100 to 150 feet in length and 20 to 40 feet in width. The ore, essentially chalcopryite, is said to contain 3.5% to 4.5% copper, with \$1 to \$2 in gold values. Two shafts, 40 and 80 feet deep, and three tunnels, from 100 to 200 feet in length, with many drift tunnels, expose the deposits at various elevations. On the surface a 500-ton smelter has been put up, also a compressor plant. On the southwest side of the peninsula the Mount Andrew copper deposits have the same manner of occurrence. A tunnel, 800 feet long, has been driven. The Copper Mountain-Sulzer properties are on the south side of Hetta inlet, in the southwest coast of Prince of Wales island. The ore occurrences in this area, though rather widely scattered, are all of copper, with a few dollars per ton in gold values. The ores are found principally along the contacts of a limestone, with either granite belts or diabase dikes. The original ores are principally chalcopryite, pyrite, pyrrhotite and magnetite, with quartz, calcite, garnet and epidote as gangue minerals. In many of the deposits surface oxidation has altered the sulphides to a considerable depth and formed carbonate and oxide ores. At the Alaska C. Co.'s prop-

erty, on the south slope of Copper mountain, development follows a contact of granite with limestone and shows the usual contact phenomena. The ledge, known as the New York, at an elevation of 3300 feet near the summit of a steep mountain slope, is exposed by large open cuts and short tunnels. At 2400 feet elevation a tunnel, 1400 feet in length, is being driven to undercut the ledge below the surface workings. A 250-ton smelter has been completed, a water power plant sufficient for all purposes has been built, besides a 5000-foot cable tram from the uppermost workings to the smelter. Two large groups of claims are being developed by the Alaska Industrial Co., namely, the Jumbo group of twenty-nine patented claims, on the north slope of Copper mountain, and the Green Monster group, 6 miles east of Copper mountain. On each of the above groups several copper-bearing ledges have been exposed by tunnels and open cuts, and on some there are large surface exposures of rich chalcopryite ore. On the Jumbo claims diabase and limestone are in most cases the enclosing rock. At the Green Monster group the deposits are more often at or near the granite limestone contact.

S. Peacock, manager of the Omar M. Co., is working the Kayram mine, Ketchikan district, with thirty men, and by July 1 his force will be increased to eighty men. W. P. Wood is engineer and J. McCallion foreman. The first work will be the construction of a mile-length tramway, connecting the wharf at the east level with the works 3300 feet above that elevation.—A. A. Wakefield has commenced work on his property adjoining the Niblack copper mine, Ketchikan. It is the intention to sink a new shaft, from which the ore body will be thoroughly explored by drifts.—The contract of the Niblack management, Ketchikan district, calls for the delivery of 50,000 tons of ore to the Tacoma smelter this season. The first shipment of this has already been made, and it is expected that several of the steamers on their down voyages will carry Niblack ores. The rate of shipment at first is expected to be about 5000 tons a month, but will increase as underground explorations are extended.

A Tacoma report says that mining operators in the Nome district, who are assembling cargoes of machinery for shipment north, say that 1000 more workmen than are now at Nome will be required in the adjacent districts during the coming summer.—J. E. Chilberg of the Pioneer M. Co. says there are five ditches to be built in the Kougark country.—W. E. Leland of California, who represents Los Angeles capital, will take north 1000 tons of machinery for use in the Solomon bay district, including a large dredger. Materials to be shipped north by the first boat will include the rails and equipment for 30 miles of railroad from Mary's creek to Davis Landing.—Navigation has been opened between Dawson and Fairbanks.—Citizens of Fairbanks are reported to have organized a vigilance committee to rid the town of desperate characters.

To open up the Copper River valley, reduce transportation rates and develop the copper and coal mines of Alaska, the Copper River & Northwestern Railway Co. has been organized in Seattle, Wash., with J. Rosene, M. Thomsen, D. H. Jarvis, J. D. Trenholme and H. Bratnoher as the board of directors. J. Rosene says that the road will run from Valdez to the Copper river and will probably be extended to Eagle. H. Deyo, chief engineer, and four assistants have been in the North since April, making surveys and mapping out a route for the new road.

### ARIZONA.

Cochise County.

(Special Correspondence).—The Vantia M. Co., operating near Benson, are putting in a new stamp mill, pump and motor. The mill will have fifteen tons daily capacity, being of the circular screen type with triple discharge and the stamps weigh 900 pounds each.—The Savage G. M. Co., operating in the Paradise district near Rodeo have purchased a 50-ton smelter which they will put in on their property. Besides smelting the Savage ores it is the intention of the company to do general custom work for the mines of the Paradise district. Benson, May 23.

The Warren district, surrounding Bisbee, is in the Mule Pass mountains near the Mexican line. This range runs east and west and consists of beds of Lower Carboniferous limestone dipping away from a central mass of porphyritic rock. The ores are found in the erosion canyons on the south side near the contact of the limestone and porphyry and formed by the replacement of the porphyry through mineral solutions. The sulphides pass in alteration into bodies of oxidized ore. Empty caves are usually found above the ore.

The Cochise Cons. Copper Co. is to put in a large concentrator at Douglas.

Gila County.

(Special Correspondence).—The Warren Copper Co. are preparing to sink a 500-foot shaft near Globe.—The owners of the United States group are preparing to start work near Globe.—A new hoist is to be put on the Gibson mine, near Globe, to sink another shaft. It is shipping 250 tons copper ore monthly. Globe, May 23.

The Arizona-Colorado Copper Belt & Gold M. & M. Co. has resumed work, 3 miles north of Globe, with eighteen men under the direction of J. Bandhauer, superintendent. A No. 7 Cameron station pump has been put in at the 200-foot level, also a blowing apparatus, and the plant has been overhauled preparatory to sinking. Work has been started in the double-compartment shaft, which will be sunk 300 feet deeper, giving a total depth of 500 feet. R. M. Forsee has been re-elected president and general manager.

Graham County.

It is announced that the Shannon Copper Co., at Clifton, will put in a new converting plant and add another smelting furnace.—F. M. Morris has shipped rich ore to the Shannon smelter from near York.—The Arizona Copper Co. is putting in a briquetting plant at Clifton to save the fines of coal and coke, mixing with pitch and compressing.

Maricopa County.

L. White reports that the work in the White gold

mine has been temporarily stopped pending the arrival of a hoist and the hauling of the tramway.

#### Mohave County.

(Special Correspondence).—The Cyclopic G. M. Co., in Gold Roads, has completed a wagon road from the mine to a connection with the Dolan Springs road, which shortens the distance to the railroad 22 miles. The company has laid a new pipe line to the springs and has put in a pumping plant to force the water over the mountain to the mill. The milling plant has been remodeled and the crushing of ore will soon be started. A hoisting plant will be started. Rich ore is reported from the Red Top mines, Weaver district.

Kingman, May 23.

The Elkhart mine at Chloride is being unwatered preparatory to sinking the 600-foot shaft. High-grade shipping ore has been struck in the lower workings of the Jersey Lily mine at Chloride. Superintendent T. B. Lamb will make a trial shipment to El Paso. The new mill belonging to the German-American M. Co. at Snowball has arrived and by July 1 is expected to be ready for work.

#### Pinal County.

The Midway mine has been taken over by Pittsburg capitalists and 300 feet of track and a car have been ordered for work in the lower levels. This mine is 1½ mile from Kelvin, on the south side of the river. An engine and boiler for the leaching plant is to be put up on the Gila river, 9 miles from Florence. The Eldermemania properties, between Ray and Kelvin, have been bonded to parties who will develop them. Manager Sharpe, of the Arizona-Pacific, reports that he has unwatered the mine at Woolley and resumed sinking.

#### Santa Cruz County.

The Springfield-Arizona Development Co., E. G. Mallette manager, is preparing to work properties near Harshaw. The Presidential mines, in the Santa Rita mountains, are putting in pumps and boilers.

#### Yavapai County.

(Special Correspondence).—The Arizona Smelting Co. has purchased of the Bradshaw Mountain C. M. & S. Co. the Val Verde smelter on the Agua Fria, south of Prescott. The main consideration is the assumption of a mortgage for \$35,000, held by the Commercial Trust Co. of Phoenix. This is the first step of the new company toward rebuilding the Val Verde smelter, the loss of which has been a hardship to miners in Yavapai county since its destruction by fire less than a year ago. The Arizona Smelting Co. has capital and will doubtless erect a modern smelter. The Geo. A. Treadwell M. Co.'s 250-ton smelting plant at Mayer is ready to blow in. It has been built for treating the ores of the company's own mines, but custom ores will be received. The company's mines, known as the Hackberry, Iron Queen and Boggs, have 10,000 feet of workings and are developed to depths of from 400 to 500 feet. They are said to be in condition to produce daily upward of 200 tons of ore carrying average values of 4% copper. Near the smelter and on the company's ground is a deposit of lime which will be used for fluxing purposes. The grade of matte turned out will be between 30% and 35%.

Prescott, May 23.

The Thumb Butte M. Co. has started work near Prescott. It is reported that they will put up a mill. A. J. Harris is putting up a new cyanide plant at the Harqua Hala mine.

It is reported that on May 22 tons of rock and earth caved in at W. A. Clark's United Verde copper mine at Jerome, the ground dropping from the surface to the 700-foot level. Cracking timbers gave the alarm and 300 miners escaped uninjured. For several days the ground had been settling and the timbers creaked. From fissures on the surface clouds of sulphur smoke arose from that part of the mine which has been on fire for several years. The extent of the damage has not yet been ascertained. The hoisting works, which are over the mine, have settled and the machinery cannot be worked. The smelting plant has also been shut down and all activity has ceased.

The Mudhole mine, on Lynx creek, southeast of Prescott, is to be reopened by the new owners. The Decatur mine, near Jerome, is being worked again.

### CALIFORNIA.

#### Amador County.

The Central Eureka shaft, near Sutter Creek, has been completed to a depth of 2400 feet, where a level is being opened up. This company has declared a May dividend of 7 cents per share, making \$28,000 in all.

#### Mono County.

Active work is reported from Masonic, near Bodie. The shaft on the Jump-Up-Joe is down 85 feet. Work has commenced on the True Friend group, under the management of F. Stewart, who will run a 100-foot tunnel to tap the ledge. On the Myrtle & Julia a shaft has been sunk 50 feet. A stage, to run tri-weekly, will be put on by H. H. Boone of Bodie, as soon as the roads are passable.

#### Nevada County.

The new 5-stamp mill at the Kenosha, formerly the Seven-Thirty mine, near Grass Valley, will soon be ready for operations. Sinking is under way. The Oustomah M. Co. of Nevada City has bought land on Wet hill, which will enable the Oustomah to drift north along the course of their vein. The Idaho-Maryland twenty stamps are crushing rock from the dump. The Orleans mine near Grass Valley has been sold to J. M. O'Brien of San Francisco, Cal.

#### Plumas County.

The main tunnel of the Lawton mine, south of Quincy, is to be driven ahead, under the direction of O. Jones.

#### Shasta County.

H. O. Cummins of Shasta is putting up a 5-stamp mill for the Middle Creek G. M. Co. at the Dobrowsky mines. The National mine on Rich gulch, near Churntown, 10 miles from Redding, is under the management of H. P. Walker.

#### Sierra County.

F. L. Taft and Wm. Daxon of Mullan, Idaho, have

started work at the Sovereign mine in Ladies canyon, near Sierraville.

Work has been started at the Diadem mine, near Forest. The drain tunnel is being repaired and pumping will be started.

#### Siskiyou County.

F. C. Perew of Los Angeles has taken an option for \$200,000 on the Taylor Lake M. Co.'s claims in the Liberty mining district, 12 miles from Etna. He expects to add more stamps to the mill and to put in an electric power plant. The Blue Jeans M. & M. Co., operating on China gulch, Liberty mining district, are crushing ore in a 2-stamp mill. J. M. Hadley, Wm. Werst and B. S. Phillips are interested.

#### Tuolumne County.

The New Calico M. Co. have started their hoist on the Lucio ranch east of Stent. J. A. Thompson is manager, J. H. Gerken superintendent, J. J. Morris foreman and A. W. Young and G. Hepper engineers. The shaft is down 140 feet vertically. The Densmore mine, near Columbia, has been bonded to H. Dible and associates for \$100,000. Work is to be started at once. The main shaft on the Don Pedro, near Cooperstown, is down 200 feet, where a station has been cut and drifting started. It is reported that a 10-stamp mill is to be put up. W. H. McClintock is superintendent. The main three-compartment shaft of the Omega, near Columbia, is down 90 feet. Work is to be resumed on the Mack near Big Oak Flat. The Santa Ysabel shaft near Stent is to be sunk 300 feet from the 800-foot level. The mill has been started on the Brindle Pup near Columbia. Crushing has been started at the 3-stamp mill of the Experimental Gulch mine near Columbia. New concentrators are being put in at the Longfellow mine near Big Oak Flat.

#### Yuba County.

The U. S. Debris Commission has secured complete rights of way for the system of training walls from Daguerre point to Marysville, and the walls will be built this year to correct the channel of Yuba river and cause it to scour and reduce its level. The walls will be built by mining dredgers without cost to the Government, the owners of the machines extracting gold from the material while building the walls.

### COLORADO.

(Special Correspondence).—The Independent smelter operating at Golden has been closed down for some time on account of shortage of ore. At a meeting held the latter part of last week it was decided to reopen the smelter. The operators in Clear Creek and Gilpin counties have agreed to throw their patronage to the Independent plant. The smelter which has a capacity of 300 tons per day has been operating only a portion of the plant and it was decided to close down until some definite arrangements could be made to secure the proper amount of ore. The United States Mint, which was to have opened July 1 for coinage purposes, will be delayed opening on account of some changes having to be made in the plant. The Gore canyon suit of the United States Government against the Moffat railroad for right of way through the canyon is attracting the attention of the State as it may involve their rights to the use of water as well as the canyon. The Denver Chamber of Commerce is probing the freight rate question and have a representative before the Senate Interstate Commerce Commission in Washington setting forth its complaint along this line. It is thought by getting the freight rates reduced to an equal footing with Eastern point, it will be a great benefit to Denver and Colorado.

Denver, May 23.

#### Clear Creek County.

The Wilcox tunnel at Silver Plume, which is being driven by the Waldorf Co. to develop their claims, has cut the Commonwealth vein, which is an extension of the Santiago lode owned by the Hazelton-Santiago Co. As soon as the new compressor is put in drifting on the vein will be commenced. The Commonwealth vein has been cut 3800 feet from the portal of the tunnel. It is reported that the Transcontinental M. Co. will put in an air compressor to drive the Vidler tunnel in East Argentine district.

Work is to be resumed on the Mammoth property on Brown mountain near Georgetown under the superintendence of B. J. O'Connell. The crosscut tunnel being driven into Leavenworth mountain near Georgetown by the Leavenworth Mountain M. Co. is in 110 feet. R. H. Blackman is manager.

A 25-ton mill is to be put in at the Santiago in the Argentine district, water being obtained from Georgetown.

#### Eagle County.

A strike of high-grade ore is reported near Pando, south of Red Cliff. Claims have been staked around the discovery.

#### Gilpin County.

J. F. Hopkins of Denver has given a lease and option on the New York stamp mill on North Clear creek to the Pewabic Con. G. M. Co. Men have been put to work and the mill will be in charge of C. Fox. The mines of the Pewabic Co. in Russell district are reported to be in good shape for furnishing the bulk of the ore supply for the mill. Chicago parties have taken a lease and bond on the Mabel property in lower Russell district, owned by C. F. Barker of Hot Sulphur Springs. T. Cudahy of Central City has been appointed manager. The group is developed by a tunnel which is in 900 feet, and which cuts the main shaft of the group, which is 250 feet deep from the surface to the tunnel and goes down a further depth of 162 feet below the tunnel. This shaft is being made a skip shaft and is to be sunk at least 100 feet deeper, and to hasten developments a 15 H. P. gasoline hoisting engine is being put in at the shaft in the tunnel. A level will be run east at the bottom of the shaft. Arrangements are being made for a resumption of operations at the main shaft of the Russell M. Co. in Russell district. F. L. Paxton is in charge. J. T. Semmens of Gilpin, and M. Edwards of Nevada, have taken a lease on the Aetna-Kent property on Quartz hill and have commenced work. The Mont D'Oro M. & M. Co., operating in the Quartz

Valley district, owns the Smuggler, Felix and New Century claims, and has a lease and bond on the Delight and Colorado Girl lodes. The group is to be opened up through the tunnel on the Delight vein, which is in 300 feet. E. C. Sherman is manager. C. Philipps and M. Dalpez & Co., operating the Dump lode on Gregory hill, near Central City, are putting in new machinery and building a new shaft house. The main shaft is 330 feet deep and sinking is being continued. The 280-foot east and west levels are being driven and a good grade of ore is cut. Martin & Co. leasing on the Pederson lode on the Bobtail hill, property of H. Sayr of Denver, are working on the 200-foot west level. The ore is being hoisted through the Puzzle shaft, which is rented for that purpose from C. E. Wiley & Co. H. H. Hall & Co. are leasing on the Mountain City lode on German mountain, 60 feet from the surface. The Independent sampler at Black Hawk has been closed. Manager J. A. Gilmour of the Chase mine in Willis gulch, near Central City, reports the cutting of a large porphyry dike 600 feet east of the shaft at a depth of 300 feet, which has opened up into 4 feet of vein matter. C. Taylor of Denver and E. Baeder of Tolland have taken a lease and bond on the Norway mine on Mineral hill, near Central City, which is developed by a shaft down 50 feet and also a 150-foot tunnel. Some good surface ores were formerly taken out of this property, but it has been idle for some time past. The lessees report a very good showing of tungsten in the lower workings. Hatfield & Wornwood are sinking a new shaft on their Gold Coin property on Baltimore ridge.

An air compressor is to be put in by the Yankee Con. M. & T. Co., operating at Lombard, in the Yankee district. The new mill of this company is to be started up and an aerial tramway is to be built from the mines to the mill.

#### Lake County.

Work has been resumed on the Sunnyside tunnel on Mt. Elbert, near Twin Lakes, under the direction of G. Miller. B. Geiger has resumed work on his claims on Mt. Elbert.

Work is to be resumed on the Buckskin group, near Twin Lakes, by G. V. Booco.

Repairing the shaft and cleaning out the drifts at the Ballard-President property, Breece hill, Leadville, has been completed, and the lessees will soon be breaking ore. C. R. Osgood and B. Ross are the present lessees.

#### La Plata County.

On the east slope of the La Plata mountains, near the head of Junction creek, the Neglected mine, in the Oro Fino district, has been operated since 1902, and a mill is working low-grade ores which can not be profitably shipped. The mine is near the head of Gaines gulch, on the west slope of Monument hill. The ore deposits in the western part of the Durango quadrangle are in red sedimentary rocks, which have been intruded by dikes and sheets of grayish-green porphyry. The ore may be developed in the porphyry, at its contact, or in the sedimentary rocks near the porphyry. Often it appears to be a replacement of the porphyry, which is altered and decomposed near the fractured zone. Both porphyry and sediments are sometimes impregnated with pyrite for a short distance away from the broken zone, and through them extend little stringers of white quartz, which carry flakes and specks of telluride. In places where the sedimentary rocks are impregnated there does not appear to be any constant difference between the development of the ore in the sandstone or in the shale. In the Neglected mine the shale is considered the most productive horizon, while in the Durango Girl the richer ores so far have occurred in the quartzite below the shale. The Neglected mine is worked through a vertical shaft from which levels running east and west have been opened at depths of 85, 125 and 175 feet. The principal ores are telluride. Native gold, pyrite, and amalgam are present. The ores of the Durango Girl mine, in Walls gulch, on the east slope of Lewis mountain, are chiefly tellurides. The Ruby claim, south of Cumberland Peak, is interesting on account of the occurrence of native mercury in the ore. In Leavenworth gulch the Porcupine Co. is developing twelve claims.

#### Gunnison County.

Mine operators of the Tin Cup district are contemplating trying traction engines as a means of ore transportation from the mines to the railroads. The Woods Investment Co. of Cripple Creek, operating the Pie Plant group in Taylor Park, are 35 miles from St. Elmo, the nearest railway point. A 100-ton cyanide plant is treating the low-grade ores. The Taylor Park M. Co. is operating 6 miles north of the Woods property. It has one tunnel over a mile in length. Its ores are shipped to Aspen, but the company intends building a big concentrator at the mine. On Italian mountain, at the head of Taylor Park, bodies of lead ore have been opened up but cannot be shipped, as there is no way to get it out except by pack trains. The Brunswick M. & M. Co., owning the Jimmy Mack at Tin Cup, has a chlorination mill that cost \$115,000, but it is said it does not treat the ore successfully, therefore it is to be taken out and a concentrating plant substituted. Water came into the Jimmie Mack and gave trouble, so the management decided to drive a crosscut tunnel into East Gold hill, from above the mill. It is now 1500 feet in length, but will have to drive some 300 feet farther. The mill will not be remodeled until the Mack vein is entered by the tunnel. The Akron M. Co. have driven the Akron tunnel at White Pine 4000 feet and have cut the May Mazeppa vein at 3700 feet and a blind lead at 3600 feet.

#### Ouray County.

Arrangements have been completed for the resumption of work on the High Bridge properties on Sneffels creek, near Ouray. The property, consisting of three patented claims, owned by J. Canavan, has been idle on account of litigation which has been settled. The High Bridge shaft will be retimbered and a shaft house and hoist put in. This shaft, to a depth of 165 feet, was sunk seventeen years ago, when water caused a tunnel to be started lower down the mountain to cut the lead at a depth of 500 feet. This had been driven 600 feet when it was found that the shaft was being gradually drained. With the departure of snow, work is to be resumed on

the James Haskens property, the Black Cave group, 3 1/2 miles south of Ouray, on the Red Mountain toll road.

#### Sao Juan County.

The Brooklyn mine in the Red Mountain district is to be worked this summer. Water power is to be substituted for steam at the Pride of the West mine, near Silverton. Diamond drilling is being continued. E. Condon has been appointed foreman. It is expected that the 50-ton stamp mill of the Hamlet mine, near Silverton, will be started June 15. This is probably the first mill ever built in the San Juan in the winter. The tramway is half completed. The crosscut of the Charter Oak on King Solomon mountain, near Howardsville, is in 450 feet, with an estimated 100 feet to drive to tap the lead.

Sinking on the main shaft at the Esmeralda, near Silverton, has been temporarily suspended and work is being rushed on the second and third levels. Drifting on the vein both ways from the shaft will be continued for some time. It is reported that a mill and cyanide plant are to be built this summer. The payroll averages twenty-five men. Manager Thompson of the Delayed M. & M. Co. on Lime creek, near Silverton, intends to put in electric drills as soon as the Rockwood power plant is in position to furnish power, and also intends to build a mill. The Trilhy tunnel, near Silverton, is in over 1000 feet. The Auburn Con. G. M. Co. are in 275 feet with their tunnel in Dome mountain, near Silverton.

The Bailey M. Co. have a lease and option to purchase on the Bandora and Little Todd mines above Silverton, near the source of Mineral creek. Men will be put to work clearing the old workings.

#### San Miguel County.

The new 60-stamp mill of the Smuggler-Union Co. is running full time and twenty stamps of the old mill are crushing rock. The Tomboy mine and mill are running full capacity. The Stillwell tunnel has cut the Liberty Bell vein at a depth of 1800 feet, 1000 feet from the old shaft. The Liberty Bell mill has been started by Superintendent Chase, after having been closed down four months, giving employment to between 200 and 300 men. The close-down was for the purpose of installing a completely new plant.

#### Summit County.

The Mary Verna and North American companies, operating in the Ten-Mile district, above Frisco, expect to have machine drills in operation on their properties soon. Work at the Abundance mine, on Mineral hill, near Breckenridge, continues with three eight-hour shifts. On account of the melting snow surface water is bothering. The shaft is down 150 feet and work on a station has commenced preparatory to cross-cutting. Sinking will not be resumed until the surface water ceases to run into the shaft. The American Gold Dredging Co., on the Swan, near Breckenridge, have started prospecting drills under direction of W. Lytle.

Work has been started on the Buffalo placer mine, below Dillon. L. Kingsbury is manager. He has also started the Summit Banner placer mine.

#### Teller County.

The drainage tunnel committee of Cripple Creek mine owners has under consideration the construction of a \$750,000 tunnel to drain the properties in the district. The proposed tunnel would be 5 miles long, 8x12 feet, and would require five years for its completion. Although the matter is still only a subject of discussion, it is thought that favorable action will be taken by the prominent mine owners of the district. The project is said to be the result of the refusal of the Portland Co. to join the other mine owners in the construction of the second tunnel planned, as that tunnel would not benefit the Portland property. It is understood that the Portland people are satisfied with the new project and will subscribe liberally. The proposed tunnel would start 1 1/2 mile below the present tunnel and run beneath the water courses of Beacon hill and the El Paso and end under the Black Belle claims, east of the Vindicator property. On Signal hill, west of Cripple Creek, the Compromise M. & M. Co. is to sink a winze on vein matter cut at the 190-foot level of the shaft. I. Barber is superintendent. A rich strike is reported in the 350-foot level of the International, on Gold hill, Cripple Creek, by Lessee Webster. The Morning Glory No. 4 of the Work Co. of Cripple Creek is being operated under lease by three sets of lessees. At the north end of the claim Lessee Wrockloff is working. On the middle block Lessee J. W. Price is making regular shipments of smelting ore. On the south end Lessee Clark and associates are developing the ground. Lessee Carter, operating the Free Coinage property, Cripple Creek, is sinking a three-compartment shaft on the Pueblo claim and will drive laterals from the 200-foot level. Ore is being raised through the Ruby shaft, Cripple Creek, from a depth of 1200 and 1350 feet, bodies at the latter depth being reached through a winze. Work is being done by the Merger Co. under the direction of Superintendent Stark. Elsherry, Cain and associates, operating on the west block of the Teutonic claim, on Ironclad hill, have put up a gallows-frame 254 feet high and are putting in a 60 H. P. boiler. The hoist will be 8x10. The shaft has been sunk to a depth of 110 feet. The Prince Albert shaft, on Beacon hill, is down 300 feet and is being pushed with twenty men and machine drills. Mayfield and associates, operating the Mary Cashen, in Victor, are drifting in the 350-foot level and taking out good ore. The Milwaukee Mutual Co., operating under lease the Mahel M. shaft of the Gold Dollar Co. on Beacon hill, Cripple Creek, will put in a larger hoist and a cage. A rich shoot has been struck on the 650-foot level. J. K. Walsh intends to continue the Forest Queen shaft, Cripple Creek, to a depth of 700 feet, where a lateral will be started. O. D. Fogelman will sink another 100 feet on the Midway claim, between Bull and Ironclad hills, Cripple Creek.

#### IDAHO.

##### Boise County.

Sluicing the gravel in the 2 miles of river bed reclaimed by the Golden Treasure M. Co. by the completion of the Ox Bow tunnel, 30 miles from Placerville, has begun. L. A. Coate is manager. The entire body of the Payette river is turned by the dam through the tunnel cut in the granite. The bore in the rock is 10x12 feet. This is running two-thirds full. Turbine wheels, dynamos, etc., for a 10,000 H. P. plant are to be put in at the mouth of the tunnel.

#### Idaho County.

Z. A. Harris of Cleveland, O., president of the Twentieth Century G. M. Co., is taking supplies and machinery in to the company's property in the Thunder Mountain district, near Roosevelt. The company intends to put in a 30-stamp mill. The company has an electric light plant for lighting the mine and mill. The mill will be put up south of the three tunnels. J. R. Noss is superintendent.

It is reported that the Thunder Mountain & Big Creek Con. M. & T. Co. has secured control of the Werdenhoff M. & M. Co., Crown M. Co., Empress M. & M. Co. East Dewey G. M. Co., Blackfoot G. M. & Dev. Co., Ltd., Dewey Ledge G. M. Co., Rainbow Mountain G. M. Co., Thunder Mountain G. M. Co., Campfire G. M. Co., Blackfoot Extension G. M. Co., and the Buffalo group of claims, between the Sunnyside and the Dewey mines. It is announced that sufficient shares of the various companies have already been secured to insure the deal going through. The officers of the combination are: J. E. Morhardt, New York, president; F. W. Hunt, Boise, Id., vice-president; James B. Pratt, New York, secretary, and E. H. High, Weiser, Idaho, treasurer. The company intends to put in a power plant and build a railroad into the Thunder Mountain district and also to build a 50-stamp mill. W. L. Lowry of Denver, Colo., has controlling interest in the Evergreen mine, on the Clearwater river, 6 miles east of Grangeville, and will put a 100-ton plant on the property.

H. H. Schieler, manager of the Idaho Con. Little Giant M. Co. of Warren, will put in an electrical transmission line to furnish power for the mine and mill. The contract calls for a 150 K. W. generator, one 75 H. P. motor and two 20 H. P. motors, transformers, etc. The larger motor is to be attached to a 75 H. P. Rand air compressor, which will furnish power for hoisting, pumping and drilling. A 5-stamp mill will be put in under the mine dumps to work the ore which has been thrown over as too low grade to hear reduction. Sampling shows that these dumps carry values above \$5 per ton. Water from Warren creek will furnish the power for the generator.

#### Lemhi County.

Work is to be resumed in the Upper Lemhi district by the Excelsior Co. of Spring mountain. In the north end of the district the Union-Lemhi Co. are doing considerable work. A. R. Nichols of Union, Fremont county, is president and W. E. Thompson of Kootenai secretary-treasurer.

#### Shoshone County.

The Roberta M. & M. Co., developing claims on Canyon creek, near Gem, is running a crosscut tunnel. A. Penaluna of Butte, Mont., is president. The shaft of the Oom Paul on Canyon creek is to be continued from the 220-foot level. An electric hoist is being put in.

#### MONTANA.

##### Fergus County.

A 100-ton mill and cyanide plant is being put up on the Maginnis mine, near Malden. It is announced that P. W. McAdow of Punta Gorda, Fla., will return to Malden to take over the operations about to begin on the Alpine claim.

The Queen G. M. Co. are boring with two diamond drills on the Bullard property at Kendall.

##### Granite County.

G. H. Savage, manager of the Milwaukee G. Ex. Co., is putting up a tramway at Red Lion, near Philipshurg, to carry ore from the Hannah mines to the new 100-ton mill.

##### Jefferson County.

The Bullion mine of the Cataract M. Co., near Basin, is shipping to the Helena smelter. The Minnesota mine, near Corbin, is being developed by M. Manuel. It is stated that development work is to be started on the Rose Gold properties in Golconda gulch, near Jefferson.

##### Lewis and Clarke County.

The shaft at the Red Bird mine, near Austin, is being sunk another 100 feet, giving a depth of 450 feet. It is shipping to the Helena smelter. It is reported that Rose & McNamara of Helena are to increase the mill and cyanide plant of the Ruby Gulch mine. The East Helena smelter of the American S. & R. Co. is running three furnaces. New roasters, with a capacity of 120 tons daily, are to be put in.

##### Silver Bow County.

Judge Hunt has denied an injunction sought by F. A. Heinze against the Parrot M. Co. in Butte to prevent its mining in a vein which he contends apexed in the Nipper mine, on the ground that a sufficient showing had not been made. In regard to the so-called "blue" vein, Judge Hunt holds that the question hinges on where the discovery is in the Nipper, and in the absence of sufficient showing he grants the injunction in that particular. The decision is considered an important victory for the Amalgamated Co. The Parrot mine has been closed since the proceedings started and will now reopen. It is reported that the Leadville M. & S. Co. has started work 18 miles north of Butte.

#### NEVADA.

##### Lincoln County.

Superintendent F. P. Swindler, of the Bamberger-DeLamar G. M. Co. at DeLamar, has been making arrangements for a slimes plant below the mill with a capacity of 750 tons daily.

The Nevada-Eldorado M. Co. has been organized to work the Silver Legion mines at Eldorado canyon. E. J. Roberts is manager. The new 60 H. P. gasoline hoist at the Quartette mine, Searchlight, has been started.

##### Lyon County.

The Bluestone copper mine, 3 miles from Yerington, has been sold to M. J. Heller and others by H. E. Miller, A. Miller and J. W. Scott. A new concentrating plant has been put in.

#### Nye County.

Plans have been completed for the smelter at Soda-ville and it is announced that construction is to be started soon.

#### Storey County.

The Sierra Nevada M. Co., through Superintendent A. J. McDonnell, is leasing to tributaries that part of its territory on Cedar hill above the Riley tunnel, near Virginia City, on what was known as the Sacramento, Meridith, Allen and other claims before they were purchased by the Sierra Nevada Company. The leases are granted for one year and pay on ore extracted, as follows: On the gross value of all ores yielding \$10 or under per ton, 10%; from \$10 to \$15 ore, 12 1/2%; \$15 to \$25 ore, 15%; from \$25 to \$50 ore, 20%, and all ores yielding \$50 or over per ton, 25%, and 10% of the assay value of all tailings from ore extracted and milled.

#### White Pine County.

Work has been started at the North Mountain mine of the Consolidated Mercur Co. at Cherry Creek, under the direction of W. S. Brown.

E. Wallace of Denver, Colo., has bought the Joanna mine, near Cherry Creek, for \$50,000. A gasoline hoist has been put in at the Brooks mine at Pilot Knob.

#### NEW MEXICO.

##### Grant County.

The National G. & S. M. Co. at Stein's Pass reports a rich strike on the Beck mine. A. C. Young has sold the Silver Bell mine, near Hachita, to F. C. Emory, secretary of the Golden Cove M. Co. of Sonora, Mex. The King M. Co. has resumed operations at Old Hachita, with H. Marmion of San Antonio, Tex., as superintendent. Detroit-New Mexico M. & Dev. Co. has commenced placer operations on Whitewater creek, 3 miles southwest of Central. The Pyramid Peak M. Co. has been organized to take over the Nelly Bly and Lee mines, near Lordsburg, and work has been resumed on the Cobra Negra and the North American mines. The shaft on the Bly has been entirely retimbered, the mine has been unwatered and sinking has commenced, the work being done by three eight-hour shifts.

##### Otero County.

The Tularosa M. & M. Co. is building a concentrator 11 miles from Tularosa on the road toward Mescalero. Development work is being done in the company's mines.

#### OREGON.

##### Baker County.

Manager F. D. Smith has driven the Zelda tunnel 100 feet from the shaft and is taking out ore being crushed in the 10-stamp mill on Snow creek, near Tipton. It is reported that Manager Kelly will order a hoist and commence sinking at the I X L near Greenhorn. The workings are down 300 feet.

T. S. Van Fleet, manager of the Gold Bug group, Red Boy district, near Granite, has returned from the East and is pushing operations at the Gold Bug. H. Blake has accepted the superintendency. The old Geiser-Hendricks Co. has been reorganized and the working capital increased from \$25,000 to \$250,000. This company owns the Taber Fraction, Midway, Platts of Cracker Creek and the Gem in the Sparta district. The Taber Fraction and the Gem are on the producing list.

##### Douglas County.

The Crystal Consolidated Co. at Bohemia is putting its mill into condition for active operations. Work is progressing on the Oregon-Colorado at Bohemia.

The Continental G. M. Co., with headquarters at Portland, and operating the Continental mine at Nugget, 12 miles from Myrtle creek, will let the contract for a mill with a capacity of fifty tons daily on June 1. W. B. Stewart is manager.

##### Jackson County.

The Sterling placer mine, 9 miles south of Jacksonville, has been sold by H. E. Ankeny of Eugene and V. Cook of Portland to a company in which F. F. Blakeley of Portland is interested. J. D. Heard will have charge of work.

##### Josephine County.

The drift on the main vein of the Martha, near Wolf Creek, has been driven 900 feet under the direction of Manager Bishop of the Greenback Co. A. Howland, superintendent of the Mt. Pitt mine, near Grants Pass, where a double-tub arrastra is operating, states that the management intends putting up a stamp mill this year. A. C. Hooper is manager.

##### Union County.

James Warde and C. C. Nepple of Baker City have bought quartz claims in the Camp Carson district, 38 miles from Hilgard, from W. M. Heughan and P. Mays, and have started development work.

#### SOUTH DAKOTA.

##### Pennington County.

The Bullion G. M. & M. Co. is preparing to build a 150-ton cyanide plant at Keystone. They will crush, amalgamate and concentrate the ores and recrush the concentrates for cyaniding. A compressor and electric power plant is to be put in. F. H. Long is manager. The Minnesota M. Co., 4 miles from Rochford, is drifting on two levels and has put in a new pump. They intend to put in a new hoist. The Golden West M. Co. has started its mill at Rochford.

##### Lawrence County.

The Clover Leaf M. Co. is developing the Uncle Sam mine, near Perry, and are crushing ore from the 600-foot level with 20 stamps. The Gladiator G. M. Co. intends to start work in Deadwood gulch, near Deadwood.

#### TEXAS.

##### Marion and Bowie Counties.

The iron ores of northeastern Texas are described in a recent bulletin of the United States Geological Survey. The area studied embraces a group of counties in the northeast corner of the brown hematite district. There is a commercial basis for the subdivision of the ore field, for the deposits in these counties are so located that any iron industries based on them must be considered as tributary to two possible distributing points—Texarkana, Bowie county, and Jefferson, Marion county.

Within the area under consideration there are five geologic formations, representing the Tertiary and Pleistocene periods. Of these only the Claiborne sands and greensands and the Sabine clays and sands are of importance in connection with the ore deposits. The ores are present in quantity and cover a large area, but they do not occur in very thick beds at any point. The deposits tributary to Queen City are 4 to 6 miles north and northwest of that town. The streams have cut through the iron-bearing beds in this district, so that the workable deposits are to be looked for only on the hillsides and hilltops. In the ravines and on the slopes, however, much loose ore has been carried down and spread as a thin coating over the surface. The thickest single ore bed opened in this section is 30 inches thick. Numerous deposits of lignite occur in this area. Along the Missouri, Kansas & Texas Railroad, from Jefferson to Dargersfield, important ore deposits occur. The principal deposits are between Lancaster and Veals Switch, northwest of Hughes Springs. The richest ores are likely to be found near the surface. The operation involved in mining is shallow stripping. The scarcity of water necessitates the working and shipping of lump ore only and forbids hydraulic mining. The location and form of the ore bodies, as well as the character of the ore, will prevent the use of steam shovels.

#### Travis County.

A new deposit of celestite, or strontium sulphate, was developed during 1904 west of Austin, in the Mount Bonnell and Mount Barker district, in the Glen Rose formation, which consists largely of even-bedded strata of different thicknesses of argillaceous, arenaceous, chalky limestones, alternating with thin strata of marly, arenaceous clay. These rocks contain undeveloped beds of Epsom salts, strontianite and other materials. The magnesium limestones are soft and of a yellow color, and alternate with softer marls of similar composition, sometimes accompanied by pockets of crystalline nodules composed of calcite, aragonite, strontianite and celestite. The celestite is found in cleavable masses of irregular shape, ranging in weight from half a pound to 100 pounds, its color varying from white to pale bluish gray. R. C. Walker of Austin, who has been developing the deposit, finds that the deeper he extends his workings into the hill the purer and more abundant is the celestite. Samples of this celestite show on analysis from 97.64% to 98% strontium sulphate. During 1904 one carload of seventeen tons of this mineral was mined and shipped to Germany. The value of celestite varies from \$20 to \$50 per ton. This was the only place in the United States where strontium was mined during 1904. No strontium salts were imported into the United States during 1904.

### UTAH.

#### Beaver County.

The shaft of the Frisco mine at Frisco is being sunk from the 200 to the 400-foot level.—Water is being hoisted from the Sulu and the Crystal Contact is being worked by D. P. Rohlfing of Frisco.

The O. K. mine, in Beaver Lake district, is being worked under lease by Jas. McKeon.—The tunnel being run to cut the ore body of the Wasatch King in Beaver Lake district is to 340 feet. J. C. Brownfield is superintendent.—D. Ferguson has charge of work at the Moscow mine, in the Star district.

#### Salt Lake County.

The Bingham-New Haven, at Bingham, is sinking a winze on the Stoddard vein 250 feet from the mouth of the tunnel.—At the Bingham Central the Whitley tunnel, now in 200 feet, is being driven for the Red Elephant vein, which is still 900 feet ahead.—The Jeff Davis tunnel is in 530 feet.

#### Sammit County.

The Ontario mill at Park City has been started on low-grade ore.

#### Tooele County.

The management of the Galena King mine will extend the Honerine tunnel from the Honerine 1000 feet to the Galena King in order to give a cheaper method in handling the ore. The proposed tunnel should cut the Ada, St. Patrick and Hercules lode. It is reported that copper ore is being opened up in the 1100-foot level of the main Honerine ledge. W. F. Snyder is manager and E. J. Raddatz superintendent.

#### Utah County.

L. Western and Webb Bros. are preparing to resume operations at the Golden Gem, in American Fork canyon.—G. Tyng, manager of the Wyoming mine in American Fork canyon, says he will not be able to commence regular shipments of ore until the middle of July due to deep snow.—The lime rock quarries and kilns east of American Fork have resumed operations after a short shut down.

### WASHINGTON.

#### Cowlitz County.

The coal on Coal creek, 12 miles west of Kelso, is being developed. The bed is from 6 to 7 feet thick, with two small partings of sand. The top bench has 12 to 18 inches of bony coal, the middle bench 2½ feet of better quality, and the lower bench 18 inches of coal, in part good. The coal bed is overlain by soft sandstone. In the mine the coal looks bright, but on exposure it loses its luster, cracks somewhat and partially slacks. Some part of it is well banded and contains small pieces of fossil resin. Analysis shows that this coal contains a high percentage of water, ash and sulphur. The coal was used in running the engine of the mine, however, and appeared to burn well.

#### Ferry County.

An incline shaft is to be sunk on the Morning Glory mine, near Republic, to develop the ore shoot carrying high silver values recently uncovered.—In the Belcher district, near Republic, the Belcher and Copper Key are being worked.

#### Okaogao County.

The Mineral Hill T. & M. Co., S. L. Boyer of Danville superintendent, is working the Triune mine at Golden camp, 7 miles from Oroville. The crosscut tunnel is in 300 feet and will be driven 400 feet farther. It has cut two quartz veins, one at 225 feet in and the other at the end of the tunnel. The 10-stamp mill has been started.

#### Stevens County.

A discovery of tungsten is reported in the Cedar Canyon district by the Roselle M. Co. W. S. Thyng, J. B. Mosley and A. Schulze, all of Spokane, are interested.

### WISCONSIN.

The zinc and lead deposits of southwestern Wisconsin are described by U. S. Grant in Bulletin 1260 of the United States Geological Survey. This region comprises Grant, Lafayette, and Iowa counties. It lies between the Wisconsin river on the north, the Illinois boundary on the south, and the Mississippi river on the west. The principal towns are Mineral Point, Platteville, Dodgeville, Darlington and Shullsburg, which are connected by railway with zinc smelters at LaSalle, Peru, and Wenoona, Ill. Some of the zinc is also smelted at North Chicago, and most of the zinc carbonates and the lower grades of the zinc sulphides are shipped to Mineral Point, Wis., where an extensive plant for the manufacture of zinc oxide and sulphuric acid is located. The important deposits of zinc and lead occur in the Galena and Platteville limestones, which comprise the surface rocks over the larger part of the region. The Platteville limestone is made up largely of nonmagnesian beds, although in its lower part there are certain magnesian strata. The thickness of the Platteville averages 55 feet. The Galena limestone is essentially a dolomite, most of which is coarse-grained and porous and occurs in beds ranging from 1 foot to 4 feet in thickness. The ore consists of galena, sphalerite, smithsonite, and iron sulphide, the last usually in the form of marcasite. The ore deposits occur in cracks or irregular openings, in apparently brecciated or very porous parts of the Galena limestone, and in small particles in certain layers of rock. These three types are frequently well-defined, though at some places they grade into one another and can not be regarded as genetically distinct. In former years, and today in some of the smaller diggings, mining was carried on in a very primitive manner for the most part. The ores were usually mined, brought to the surface by hand and were cleaned by cobbing or by hand jigging. The present development of the region is due in great part to the introduction of improved methods of mining and of concentrating the ores. During the last three years 30 concentrating mills have been put up. There is good reason to believe that the bodies of sphalerite below the level of ground water will last for many years and that a considerable mining industry will be carried on here. The present high prices of lead and spelter, coupled with the fact that the lower grades of sulphide ores can be brought up to higher grades by roasting and magnetic separation, make the outlook promising. In selecting an area for prospecting care should be taken to choose one that has, below the level of ground water, a reasonable thickness of ore-bearing rock—that is, of Galena limestone, or, in the eastern part of the region, of the upper member of the Platteville limestone. Expensive explorations below the Platteville limestone are not recommended. It is suggested that preliminary explorations be made by drilling rather than by sinking expensive deep tests pits and shafts.

### FOREIGN.

#### AUSTRALIA.

##### New South Wales

The Delprat process for treating the zinciferous ores of the Broken Hill Proprietary mines, after passing through the usual experimental stage, now seems to be realizing all that was hoped for it by the inventor, D. G. Delprat, the manager of the property. Salt cake is crude sodium sulphate. It is made by treating common salt with sulphuric acid. If less sulphuric acid is added than is required to decompose the whole of the salt, then sodium chloride and sulphate of sodium will be the main products; but if excess of sulphuric acid is used, then bisulphate of sodium or acid sulphate of sodium and the normal sulphate will be the main products. In practice the salt cake obtained contains from 95% to 96% of sodium sulphate, and the remaining 4% to 5% is mainly sodium hydrogen sulphate; traces of undecomposed salt and other materials remain. In some specifications Mr. Delprat adds sulphuric acid to this solution; in others he claims sodium bisulphate as the active ingredient. The crude sodium sulphate is added to the solution until the specific gravity is stated to be approximately 1.4; in other words, the solution must be practically saturated. Mr. Delprat's solution, therefore, is made up with two objects in view, the first being to raise the particles of sulphides by the attachment of gaseous bubbles, and the second to densify the solution so as to enable each bubble to support a greater load. One strange feature about the "salt cake" process as carried on at the Proprietary mine is that a large sulphuric acid plant has been erected to supply the necessary acid for working it. The sulphur dioxide is produced by the Carmichael-Bradford process, and from this sulphuric acid is made in the ordinary way. Gypsum and sulphides of lead and zinc, with a small amount of siliceous material, is made into small balls, placed in a converter and heated; afterwards a current of air is blown through, when sulphur dioxide is given off, and the action continues as long as excess of sulphur is present. The gypsum required for the process is obtained within 5 miles from the Hill. It consists of hydrated sulphate of lime. On being heated to a temperature from 120° to 130° C. it is converted into plaster of Paris. On raising the temperature to 200° C., the anhydrous sulphate is formed. This product, from which nearly 21% of water is driven, when moistened with water sets slowly and returns to the original state. After dehydrating, the powdered sulphate of lime is mixed in the following proportions with slimes and concentrates: Slimes, 3 parts by weight, concentrates 1 and gypsum 1, or 60% slimes, 20% concentrates and 20% gypsum, the last becoming 16 or 17 parts when heated, owing to loss of water. The sulphur contents of the mixture vary from 13% to 15%. The whole of these materials are mixed and moistened with water, then passed through a pug mill. The small amount of water used serves to partly set the product, owing to the sulphate of lime becoming partly hydrated. This also serves to bind the

mixture together. The whole lot is spread out on a drying floor and broken into pieces not exceeding 2 inches in diameter. It is allowed to stop there until all surface moisture has been evaporated by the joint action of wind and sun. When dry it is shoveled into the converter. A cover is luted on to the converter. This cover is connected onto a horizontal flue by means of a telescopic pipe. Three converters in line are attached to the same flue. A couple of nitre pots are placed farther along the flue; these connect with the leaden chamber, having a capacity of 40,000 cubic feet. The success of the "salt cake" process and also the manufacture of sulphuric acid has opened up great possibilities for the Broken Hill mines. Mr. Delprat recently stated that the mines of Broken Hill turned out ore annually which contained 200,000 tons of zinc, or more than one-third of the total zinc annually produced.

#### Victoria.

The progress of the gold dredging industry in the State continues to be widely discussed, and it is probable that a further extensive development may take place during the present year. At the new Chum Railway mine there has been another discovery in the new formation in the center of the country winze, 306 feet below the 3586-foot crosscut. The stone is well mineralized, and shows nice specks of gold. The manager is of opinion that the company has intersected the top of a new formation, and that the stone so far uncovered is of a payable character. If the supposition that they have cut the top of the reef be correct, as "legs" invariably carry the best gold, the development would prove one of the most important events in the history of the gold fields. The discovery of a payable formation at such a great depth as 1172 feet from the surface has naturally had the effect of reviving the interest of capitalists in many neglected properties in which similar results are regarded as being more than probable. Victorians are impressed with the possibilities of the Bendigo district, notwithstanding the extent to which it has been worked during the last fifty years. The State mining department has mapped out the northern extension of the lines of reef, and guide posts will be erected for the information of companies and investors. The idea is to provide that companies shall have no difficulty in locating the most suitable sites for their shafts. They will now be able to tell to a very few feet the point at which they should start sinking. In the course of time a survey of the southern extension of the lines of reef will be proceeded with, and the same facilities will be afforded to prospectors and investors at the end of the field.

E. J. Dunn, director of mining, who has originated and supervised the system, thinks there is unlimited scope for the investor in Bendigo. The people, he says, do not even now grasp the possibilities which he set forth in the report on the field which he prepared for the mines department some years ago. Nowadays, with the knowledge which has been obtained by years of work, prospecting is comparatively easy, and no money should be thrown away. As for the deep ground, the fact that at the New Chum Railway mine gold-bearing stone has been discovered at a depth of 1162 feet is very encouraging. All indications are favorable to important developments at great depths. The Victorian State Premier has announced his intention of abolishing all mining royalties. A rich patch of gold-bearing country has been opened up near Mount Tara, 9 tons of stone yielding 82 ounces 11 pennyweights of smelted gold, exclusive of that obtained from the slimes.

### CANADA.

#### BRITISH COLUMBIA.

##### Boundary District.

G. H. Collins, superintendent of the Montreal & Boston Con. properties at Phoenix camp, has closed the several mines pending an examination. The mines affected are the Brooklyn, Rawhide and Stenwinder. The pumps have not been pulled and the mine will be kept free of water until examined by experts. The number of men affected is between 200 and 250 at the mine and smelters. There are reports of a sale of the property.

—Boundary shipments for the week ending May 20 were as follows: Granby mines to Granby smelter, 13,005 tons; Mother Lode to British Columbia Copper Co.'s smelter, 3456 tons; Brooklyn to Montreal & Boston smelter, 2161 tons; Rawhide to Montreal & Boston smelter, 732 tons; Mountain Rose to British Columbia Copper Co.'s smelter, 99 tons; Dominion Copper Co. dump to Trail smelter, 60 tons; Emma to British Columbia Copper Co.'s and Nelson smelters, 132 tons; Oro Denoro to Granby smelter, 99 tons; Last Chance to Montreal & Boston smelter, 61 tons; total shipments for the week, 19,755 tons; total for the year, 364,038 tons. District smelters treated the following tonnage for the week: Granby smelter, 13,350 tons; British Columbia Copper Co.'s smelter, 4228 tons; Montreal & Boston smelter, 2954 tons; total treatment for the week, 20,536 tons; total for the year, 370,509 tons.

M. Folkanham, manager in charge of the work at the Seattle mine at Brown's camp, reports that the ore in the tunnel is improving. The steam drill is making good progress.

##### Nelson District.

As a result of the outcome of the trial of J. R. Roherts, the Silver King, Poorman and Granite mines, near Nelson, and other Silverton properties operated by M. S. Davys have been closed down. If they are started up again, it will be with non-union labor.

##### Rossland District.

The tonnage of ore shipped from and crushed at the Rossland mines for the week ending May 20, and for the year, was as follows:

	Week.	Year.
Le Roi.....	2,175	51,480
Center Star.....	1,740	35,000
War Eagle.....	1,350	25,530
Le Roi No. 2.....	90	2,893
Le Roi No. 2 (milled).....	.....	2,800
White Bear.....	.....	1,100
White Bear (milled).....	350	3,980
Junco.....	240	2,623
Spitzee.....	90	3,681
Velvet-Portland.....	.....	1,977
Totals.....	5,975	134,059

A winze is being sunk from the 100 to the 200-foot

level of the Spitzee at Rosslund.—It is reported that the White Bear will be closed for three months until adequate electric power can be put in.—Stevenson, Howard & Johnson have leased the R. E. Leo group at Rosslund from the R. E. Lee Gold Mines for a year, and have begun work on the properties. They are prospecting the ledge on the surface to determine the best method of operating.

#### Vancouver Island.

(Special Correspondence).—The Tyee Copper Co.'s smelter returns for April were as follows: Smelter ran sixteen days and smelted 3324 tons of Tyee ore, giving a return, after deducting freight and smelting charges, of \$47.106.

Duncans Station, May 19.

### MEXICO.

#### Sonora.

At Mina del Oro, in the Ures district, 16 miles east of Poza, the Porvenir de Sonora M. Co., J. Henderson, manager, have completed a new reduction plant and hoist.—The Sombretillo M. Co., C. F. Folman, manager, is putting in a 30-ton cyanide plant south of Sasabe in the Altar district.

#### Zacatecas.

The 50-stamp mill of the Mozquital gold mines at Mezquital del Oro have been remodeled and completed and a new steam hoist is being put in. M. Cockerell is manager. The total working costs for mining, milling and cyaniding do not exceed \$3.75 gold per ton. Four levels below the main adit tunnel are being unwatered, each 80 feet in depth, and the first and second of which are 1500 and 820 feet respectively in length.

### PHILIPPINE ISLANDS.

The fifth annual report of the Philippine Mining Bureau states that gold has been found in almost every island of importance of the group. It has been worked by natives in placers and in stringers. R. von Drasche, a German geologist who has done some field work in the islands and has published papers upon Philippine geology, states that at the time of his visit to Mambulao and Paracale (Camarines province) there were over 700 natives working the placer deposits for gold. It was estimated by a Spanish governor of Manila of the seventeenth century that the annual output of gold from Camarines Norte was \$200,000. The natives in no part of the islands have been able to dredge or sluice, nor have they penetrated more than 50 or 100 feet into the rock at any place. In the northern part of Masbate, near Aroroy, three American mining companies have staked out and recorded a large number of placer and lode claims, and work is going on upon these at the present time. A number of placer claims have been staked and recorded by Americans in the headwaters of the San Mateo river in Rizal. In the Pigtao region of northern Mindanao it is estimated the value of the gravels to be from 15 to 25 cents to the cubic yard. Gold has been worked by the natives in Fidelisan, Bontoc province; Suyoc, Dugon and Tuboc, Lepanto province; Acupan, Tabilio, Capunga and Itogas, Benguet province; Capan and Penaranda, Nueva Ecija province; the Islands of Polillo and Cataduanes, Labo, Capalongan and Maculabo, in the Camarines; Atimonan, in Tayabas; and in Cebu, Panay, Samar and Panay. The gold from Benguet, Lepanto, Surigao and Misamis has been found in small seams or stringers in quartz, although true veins have been found in all of these districts save the last. The most promising veins from Mambulao and Paracale are reported to be contact veins between gneiss and diorite. The best-defined veins appear to be entirely in the older crystalline rocks; those of the Camarines and Masbate notably so. There are deposits of low-grade, free-milling, and partially or wholly refractory ores in Lepanto and Benguet. Copper has been reported from the Islands of Luzon, Mindoro, Masbate, Panay and Mindanao, but the only important deposits so far known are those of the district of Mancayan, Lepanto province, in northern Luzon. The report of copper in the Island of Balahac, the Paragua group, could not be verified by the mining engineer of this bureau in a recent visit by him to that island. Samples of native copper, said to have been brought from Masbate, have been shown to the present Chief of the Bureau, but no information of value was obtained from the prospector exhibiting them. The copper deposits so far known in Mindoro are all of copper pyrites, apparently of limited extent; and of the ores reported from Mindanao nothing is known. There are veins of chalcocite in the Camarines and in Bontoc, but they have not yet been prospected or developed and data concerning them are not available at the present time. The important deposits at Lepanto are at Suyoc and Mancayan, in the southern part of the province. These veins carry the sulphides, arsenides and antimonides of copper, among them enargite, and its variety first identified here, luzonite. From samples obtained in the breasts of old workings at Mancayan it has been estimated that the ores average 16% in copper, with a gangue of quartz. The working and smelting of the ores of Mancayan were carried on by the Igorrotes of Lepanto before the Spanish conquest. The metallurgical treatment was so ingenious, complicated and effective that it unquestionably points back to an older contact with civilization, probably with the Chinese from the north. The mining, of course, has been most avaricious and the old workings will require thorough timbering before modern methods of exploitation can be employed. But little is known of lead deposits in the islands, and there is reason to believe that their distribution is not wide. Crocoite, the chromate of lead, occurs with gold ores in the Camarines, but it has not so far been found of economic importance. Galena, the sulphide and common ore of lead, has been found in Bontoc, the Camarines, Marinduque and Cebu. Silver ores have not yet been discovered in the Philippines. The silver occurring here is in argentiferous galena or alloyed with the gold. The Mining Bureau is now investigating an occurrence of platinum in the gold gravel deposits of Rizal. From present information platinum and associated rare metals do not seem to be of sufficient amount in these sands to be of economic importance; but the

identification of platinum in the Philippines, after many reports of its occurrence hitherto unconfirmed, may lead to renewed search in similar fields. Zinc has so far been found only as sphalerite in unimportant and unwelcome amount in a few of the gold veins of the northern Camarines. Tin has not yet been discovered in the Philippines. A large deposit of rich manganese ore has recently been found upon the Island of Masbate, but at the present time no details of its occurrence are at hand. Important deposits of magnetite and hematite are found in Abra province, in San Miguel and Angat, Bulacan, in Bosoboso, Rizal, and in the Camarines. The deposits of Bulacan are extensive and can be readily worked. Several of the ores are suitable for the manufacture of Bessemer steel, and one of the Angat ores is notable in that it contains cobalt in appreciable amount. The natives of San Miguel and Angat have worked these ores in small charcoal furnaces for over a century and have established a good reputation and trade for the plowshares they produce. Specimens of the sulphide of antimony, stibnite, were found in small quantities in a nipa house on the south slope of Mount Maquiling in Batangas. The most important of the mineral resources of the Philippines is probably the best grade of lignite coal. This is of Tertiary age and similar in all most important respects to that of Wyoming, Washington and Japan. The best coal is free from sulphur and relatively low in moisture and ash. It is known in the Island of Batan, Albay province; in Bulalacao and Samarara, southern Mindoro; in Danao and Compostela, Cebu; on the Gulf of Sibuguey, in southeastern Mindanao; at Calatrava, Negros; and at Bislig, in eastern Mindanao. Some of the coal of Abra, Rizal and eastern Negros is also believed to be suitable for use in steamships and in stationary furnaces now burning Japanese and Australian coal. A division must be made between the jet black, comparatively hard coals, probably of Eocene age, and the brown wood coals, much softer and more friable, of later age, and in large part not suitable for transportation. Both coals contain pyrites in some seams or portions of seams, but the black coal can, in most cases, be mined free from sulphur in this objectionable form. The brown coals are not of sufficient value, compared with older coals, to justify the expense of working at the present time. The best black coals are many of them strong enough for transportation, can be mined at reasonable cost, and presumably at a good profit, and should largely take the place of imported coals in the Philippines. Their fuel value is from two-thirds to three-fourths that of the best Welsh coal, very little short of that of the Australian, and equal to that of many of the Borneo and Japan coals, which they strongly resemble. The thickness of the seams of the black coal varies from a few inches to 18 feet. A very large number of the best seams are from 3 to 5 feet thick. They lie with variable dip from 0° to nearly 90°, and in some fields the beds are irregular, twisted and faulted. Careful and thorough prospecting with drill, such as is being carried on by Lieutenant Wigmore in Batan, should precede extensive development in most of the fields of the Philippines. Sufficient mining has already been done in the Danao and Compostela coal fields of Cebu to demonstrate the value of the deposits there. Petroleum has been found in Tayabas province, where it is understood some development is now going on, and at Toledo, Asturias, and Alegria, on the west coast of Cebu. A well was operated for a short time in Toledo, but since the war work has not been resumed. The sulphate of lime in the form of crystalline gypsum and gypsum earth is found in Rizal, Laguna and other provinces of the islands. Much of this might be calcined for the production of "land plaster" and plaster of Paris, but none of it seems to be so used. Large and important deposits of limestone are found throughout the islands. In many provinces the rock is quarried and calcined, producing excellent lime that brings a very good price. White clays, or kaolin, have been found in the Provinces of Abra, Camarines, Ilocos Norte, Antique, Benguet, Cagayan, Isabela, Laguna, Marinduque, Masbate, Pampanga, Pangasinan, Albay, Romblon and Zambales. The suitability of these for the manufacture of porcelain and china is now being investigated. Red clays, from which natives make large amounts of pottery for local use, are found in almost every province in the islands. The statistics and technology of this important industry are under investigation at the present time. Fire clay has been found in the coal beds, and may afford a profitable industry in the future. Red brick are made in large quantities in Bulacan, Capiz, Rizal, Ilocos Norte, Isabela, Marinduque, Masbate and Pampanga.

### Personal.

R. C. VIDLER has returned to Silver Plume, Colo., from London, England.

T. H. LEGGETT and W. A. Pritchard have been examining mines in Spain.

J. C. LEWIS of Portland, Or., has been appointed State engineer of Oregon.

W. P. O'MEARA of Salt Lake City, Utah, has been visiting San Francisco, Cal.

J. N. SCOTT has been appointed manager of the Dundee M. Co., near Nelson, B. C.

A. W. WARWICK has resigned the editorship of the Mining Reporter, Denver, Colo.

R. S. BRADLEY of Boone, Iowa, has been at the Triune mine, Okanogan county, Wash.

L. HUNDESEN, M. I. M. M., has returned to London from the Dutch East Indies.

ED. BEEDLE has been appointed foreman in the Oustomah mine near Nevada City, Cal.

F. M. MOTT of Oakland, Cal., is manager Los Cochis M. Co. at Los Cochis, Sonora, Mexico.

J. NELSON has been elected manager Nelson mines in Elkhorn district, near Park City, Utah.

J. H. LEISHMAN is manager Wide West M. Co., Cherry Creek, White Pine county, Nev.

E. BAMBERGER, manager Daly-West mine, Park City, Utah, has been visiting in Seattle, Wash.

L. EGGERS is superintending the building of a cyanide plant for the Los Reyes M. Co. Pecos, Mex.

J. V. BOHN has been appointed superintendent of the Mammoth M. & P. Co. at Mammoth, Mont.

F. S. WILHELM of Chicago, Ill., has been elected general manager Arispe M. Co., Cananea, Mexico.

W. E. THORNE, manager Snowstorm Hydraulic Co., Fairplay, Colo., has returned there from Denver.

F. J. HARD, manager Vesuvius mine at Bohemia, Or., has returned to the mine from a visit to the East.

D. A. LYON has been made assistant professor of geology and mining at Stanford University, California.

H. M. RAE has been elected president and general manager North Moccasin G. M. Co. at Kendall, Mont.

FRED G. FARISH has returned from Sinaloa, Mex. and is at present at the Creston-Colorada, Torres, Sonora, Mexico.

J. AUGUSTINE, superintendent Berlin mine near Baviacori, Sonora, Mexico, has returned to the mine from Minnesota.

CHAS. BROCKINGTON will be retained as superintendent and W. J. Connors as foreman Orleans mine, Grass Valley, Cal.

J. N. CONNER has been appointed superintendent of the smelter of the American-Mexican M. & D. Co., Velardena, Mex.

D. HARTLEY has been elected superintendent Union M. Co., working placer ground at Reservoir hill, near Placerville, Cal.

R. H. CHANNING, manager Utah Con. mine at Bingham, Utah, is in New York City conferring with officials of the company.

O. B. STEEN, field expert Southwestern Securities Co. of Los Angeles, Cal., has been examining mines at Searchlight, Nev.

W. F. COLLINS of Chicago, Ill., has been appointed manager Keystone-Holy Terror G. M. Co., working near Keystone, S. D.

C. E. LENTZ of Twin Bridges, Mont., manager Lentz G. & C. M. Co., has been attending a stockholders meeting at Pittsburg, Pa.

O. HERLOCKER has resigned as superintendent Highland mine, near Sumpter, Or., and will devote his attention to his own properties.

H. F. WELLS of Boston, Mass., and W. H. Stearns of Providence, R. I., have been examining the Lexington Hill mine, near Deadwood, S. D.

A. C. MASSAY has resigned as superintendent Model G. M. Co., McCabe, Ariz., to become superintendent Richenbar M. Co., Richenbar, Ariz.

C. D. ROOKLIDGE has been elected secretary and manager Nevada-Superior M. Co., operating in Antelope mining district, Humboldt county, Nev.

L. C. MONAHAN has been acting superintendent Mammoth mine, near Kennett, Cal., during the temporary absence of Superintendent A. P. Anderson.

J. C. FLESCHE has resigned from the Rhoderick Dhu M. Co. and will devote his time to managing the Pewabic Con. M. Co., operating in Russell district, Gilpin county, Colo.

P. KENYON has resigned as assistant superintendent Mazatl Copper Co.'s mines, Mexico, and has been appointed mine captain Zaruma mines, Zaruma, Ecuador, South America.

JNO. H. LEWIS of Portland, Or., has been appointed State Engineer for Oregon, for four years at \$2400 per year, to co-operate with the Federal Government in irrigation and reclamation work.

ERNEST McCULLOUGH, second vice-president Northwest Cement Products Association, has resigned as engineer Municipal Engineering & Contracting Co. of Chicago, to go again into private practice as a consulting engineer in Chicago. His specialties will be concrete work and municipal improvements.

### Books Received.

Bulletin 264 of the U. S. Geological Survey, "A Record of Deep Well Drilling for 1904," by M. L. Fuller, E. F. Lines and N. C. Veatch, is published as a guide for future drilling in the regions discussed and to give knowledge of the rock succession and structure.

"Proceedings of the American Institute of Electrical Engineers," Vol. XXIV, No. 5, May, 1905, presents papers and discussions on "Time Limit Relays," by G. F. Chellis, "Duplication of Electrical Apparatus to Secure Reliability of Service," discussion on "Line Construction for High Pressure Electric Railroads," and "High Pressure Line Construction for Alternating Current Railways," and "Limits of Injurious Sparking in Direct Current Commutation," by T. Reed.

Bulletin No. 19 of the North Carolina Geological Survey describes "The Tin Deposits of the Carolinas," by J. H. Pratt and D. B. Sterrett. The principal deposits are the Rose mine at Gaffney, South Carolina, and the vicinity of Kings Mountain, North Carolina. After describing the geological and mineralogical occurrence of these veins, the authors give a summary of the tin de-

posits of the United States and of the world, together with information on the metallurgy and use of tin. It may be obtained from State Geologist J. A. Holmes, Chapel Hill, N. C.

"Bi-Monthly Bulletin of American Institute of Mining Engineers," May, 1905. C. K. Leith gives "A Summary of Lake Superior Geology, with Special Reference to Recent Studies of the Iron Bearing Series;" J. E. Johnson describes "An Automatic Stock Line Recorder for Iron Blast Furnaces;" S. S. Wyer writes on "Gas Producer Power Plants," "The Testing of Gas Producers," and "Bibliography of Gas Producers;" L. Addicks speaks of "The Effects of Impurities on the Electrical Conductivity of Copper;" H. V. Pearce describes "Improved Method of Slag Treatment at Argo." Discussions on some former papers are published.

## Commercial Paragraphs.

THE new tire mill put in by the Chrome Steel Works at Chrome, N. J., is ready to commence rolling ring dies, roll shells, Huntington rings and Chilean rings and tires from solid chrome "admantine" steel ingots.

THE Homestake Co. of Deadwood, S. D., has placed an order with the Ingersoll-Sergeant Drill Co. for what is said to be the largest mine compressor in the world. It will be used to operate fourteen compressed air mine locomotives, it being the intention of the Homestake to displace the mules now used for underground haulage with these motors.

THE Navy Department has placed an order with the Ingersoll-Sergeant Drill Co. for a Class "GC" air compressor to be located at the Portsmouth, N. H., Navy Yard. The compressor has compound steam cylinders 19 and 35 inches in diameter, compound air cylinders 32 and 20 inches in diameter and 24-inch stroke. Its capacity is 2179 cubic feet of free air per minute.

THE Trump Mfg. Co. of Springfield, Ohio, report that they have just closed a contract with an electrical concern in Illinois for six of their largest vertical type turbines, this being a duplicate contract of one placed with them some time ago. They write: "When the above contract is finished we shall have supplied this company with twelve Trump turbines. A paper mill in Massachusetts has just placed orders with us for five of our largest size horizontal type turbines. We will also furnish an electric railroad in central New York a pair of our largest size horizontal wheels in steel case. The above orders, together with a large number upon which we are already at work, have our plant running to its full capacity."

THE Dearborn Drug & Chemical Works have signed a long lease for a suite of six offices, comprising the north-west wing, on the eighteenth floor of the new Barclay building, 299 Broadway, New York City. This gives a north, west and south view overlooking all of New York harbor, North river, shores of New Jersey, and uptown New York; one of most beautiful birds' eye views in the city. When visiting New York you are invited to call at the new Dearborn offices. The selection of this new location became necessary due to the great increase of business in exports, marine, and through the branch offices at Havana, Boston, Philadelphia, Buffalo, etc., all of which come under the New York office direct. It is the company's intention, within one year, to establish complete analytical laboratories at New York to relieve the Chicago laboratories of the marine and eastern work. Arrangements have been made with the owners of the building to provide suitable quarters for this purpose above the offices, with private stairs connecting same.

## Trade Treatises.

Bulletin No. 52 of the Crocker-Wheeler Co. of Amper, N. J., describes direct current railway generators.

"A Few Words About Electric Fans," is the title of bulletin No. 54 from the Crocker-Wheeler Co., Amper, N. J.

The Franklin compressors are finely illustrated and described in a booklet issued by the Chicago Pneumatic Tool Co., 1010 Fisher Building, Chicago, Ill., and 95 Liberty street, New York.

The Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City, describe the use of their labor saving tools operated by compressed air in "Track Laying on the Williamsburg Bridge," Bulletin 2002.

The Chrome Steel Works of Chrome, N. J., G. W. Myers, Kohl Building, San Francisco, Cal., Pacific coast representative, have issued a neat brochure setting forth the use and merits of chrome steel in crushing machinery.

In "Cyanide Tank Equipment" the Redwood Manufacturers Co., 8 California street, San Francisco, Cal., have issued a catalogue valuable to every one interested in the cyanide process. Tanks, classifiers, filter bottoms, zinc boxes and lathes, valves and all machinery necessary for cyaniding are finely illustrated and described, the whole forming a practical treatise on the subject. The catalogue will be sent upon application.

The 108-page standard size (6x9 inches) catalogue of the Pelton Water Wheel Co., San Francisco and New York, is a good example of what such a trade treatise should be and a further exponent of what is possible in that direction. It is copyrighted, as it deserves to be, and contains so much of technical detail, practical information and general knowledge regarding water wheel construction and all incident thereto as to deserve a place on the desk of every one in any way interested in the subject.

## Latest Market Reports.

SAN FRANCISCO, May 26, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 27<sup>1</sup>/<sub>2</sub>d (standard ounce, 925 fine); New York, bar silver, 59<sup>1</sup>/<sub>2</sub>c, refined (1000 fine); San Francisco, 59<sup>1</sup>/<sub>2</sub>c; Mexican dollars, 47c, San Francisco; 45c, New York.

COPPER.—New York: Standard, \$15.00; Lake, 1 to 3 casks, \$15.00@15.00; Electrolytic, 1 to 3 casks, \$15.00; Casting, 1 to 3 casks, \$14.75@14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: \$64 10s spot per ton.

The total visible supply of copper on May 1, 1905, as reported by James Lewis & Son of Liverpool, England, was 18,055 tons. A small gain has been made on the stock on hand owing to about 1200 tons of copper and matte which are held up by a strike of workmen at the Cape Copper Co.'s works and cannot be smelted. The total visible supply is larger than on April 1, 1905, by just about the amount thus held. The total supply has gained about 1200 tons since January 1 last, and is nearly 6000 tons greater than a year ago, but with the price considerably higher—£70 5s, as against £63 15s.

Following are the figures for the German consumption of foreign copper for the months of January-March, 1905, compared with the same period of time for 1904-1903:

	1905.	1904.	1903.
Imports, tons.....	24,668	29,624	19,590
Exports, tons.....	3,173	1,958	3,942
Consumption, tons..	21,495	27,666	15,648

Out of the above, 20,255 tons were imported from the United States.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12; San Francisco, \$3.70, carload lots; 4<sup>1</sup>/<sub>2</sub>c 1000 to 4000 lbs.; pipe 6<sup>1</sup>/<sub>2</sub>c, sheet 7, bar 5<sup>1</sup>/<sub>2</sub>c; pig, \$4.85. London: £12 5s <sup>1</sup>/<sub>2</sub> long ton.

SPELTER.—New York, \$5.55; St. Louis, \$5.70; London, £23 12s 8d <sup>1</sup>/<sub>2</sub> ton; San Francisco, ton lots, 6<sup>1</sup>/<sub>2</sub>c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.00@30.35; San Francisco, ton lots, 31<sup>1</sup>/<sub>2</sub>c; 500 lbs., 32c; 200 lbs., 32<sup>1</sup>/<sub>2</sub>c; less, 33<sup>1</sup>/<sub>2</sub>c; bar tin, <sup>1</sup>/<sub>2</sub> lb., 35@37<sup>1</sup>/<sub>2</sub>c. London, £136 15s.

PLATINUM.—San Francisco, crude, \$18.50 <sup>1</sup>/<sub>2</sub> oz.; New York, ingot, \$19.50 <sup>1</sup>/<sub>2</sub> Troy oz. Platinum ware, 75@82c <sup>1</sup>/<sub>2</sub> gram.

QUICKSILVER.—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 <sup>1</sup>/<sub>2</sub> flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6<sup>1</sup>/<sub>2</sub>c; extra, 17<sup>1</sup>/<sub>2</sub>c; genuine, 32<sup>1</sup>/<sub>2</sub>c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, <sup>1</sup>/<sub>2</sub> lb., 50c; dust, <sup>1</sup>/<sub>2</sub> lb., 10c; sulphate, <sup>1</sup>/<sub>2</sub> lb., .04c.

NICKEL.—New York, 55@60c <sup>1</sup>/<sub>2</sub> lb.; ton lots, 40@47c. ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c <sup>1</sup>/<sub>2</sub> lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.25@16.25; gray forge, \$16.00; San Francisco, bar, 3c <sup>1</sup>/<sub>2</sub> lb., 3<sup>1</sup>/<sub>2</sub>c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@25.00; open hearth billets, \$23.00@25.00; San Francisco, bar, 7c to 12c <sup>1</sup>/<sub>2</sub> lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6<sup>1</sup>/<sub>2</sub>c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 4c <sup>1</sup>/<sub>2</sub> lb. above keg price in 1 and 5-lb. tin cans, 100 lbs. per case, 4c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6<sup>1</sup>/<sub>2</sub>c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city <sup>1</sup>/<sub>2</sub> bbl. CEMENT.—Imported, \$2.15@2.65 <sup>1</sup>/<sub>2</sub> bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 <sup>1</sup>/<sub>2</sub> bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILES.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00@shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7<sup>1</sup>/<sub>2</sub>c; Hallett's, 7<sup>1</sup>/<sub>2</sub>c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9<sup>1</sup>/<sub>2</sub>c; 100-lb. lots, 10<sup>1</sup>/<sub>2</sub>c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15<sup>1</sup>/<sub>2</sub>c; less than one ton, 17<sup>1</sup>/<sub>2</sub>c. No. 1\*, 60%, carload lots, 13<sup>1</sup>/<sub>2</sub>c; less than one ton, 15<sup>1</sup>/<sub>2</sub>c. No. 1\*, 50%, carload lots, 11<sup>1</sup>/<sub>2</sub>c; less than one ton, 13<sup>1</sup>/<sub>2</sub>c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9<sup>1</sup>/<sub>2</sub>c; less than one ton, 11<sup>1</sup>/<sub>2</sub>c. No. 2\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c <sup>1</sup>/<sub>2</sub> set; 14 oz., 40s., 9<sup>1</sup>/<sub>2</sub>c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c <sup>1</sup>/<sub>2</sub> lb.; carloads, 23@23<sup>1</sup>/<sub>2</sub>c; in tins, 30c; soda ash, \$2.00 <sup>1</sup>/<sub>2</sub> 100 lbs.; hyposulphite of soda, 3@3<sup>1</sup>/<sub>2</sub>c <sup>1</sup>/<sub>2</sub> lb.;

caustic soda, in drums, 3@3<sup>1</sup>/<sub>2</sub>c <sup>1</sup>/<sub>2</sub> lb.; Cal. s. soda, bbls., \$1.10@1.20 <sup>1</sup>/<sub>2</sub> 100 lbs.; sds., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6<sup>1</sup>/<sub>2</sub>@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2<sup>1</sup>/<sub>2</sub>@2<sup>3</sup>/<sub>4</sub>c; powdered sulphur, 2<sup>1</sup>/<sub>2</sub>@2<sup>3</sup>/<sub>4</sub>c; flour sulphur, French, 2<sup>1</sup>/<sub>2</sub>@—c; alum, \$2.00@2.25; California refined, 1<sup>1</sup>/<sub>2</sub>@2c; sulphide of iron, 8c <sup>1</sup>/<sub>2</sub> lb.; copper sulphate, 5<sup>1</sup>/<sub>2</sub>@5<sup>3</sup>/<sub>4</sub>c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1<sup>1</sup>/<sub>2</sub>@2c <sup>1</sup>/<sub>2</sub> lb.; nitric acid, carboys, 8c <sup>1</sup>/<sub>2</sub> lb.

OILS.—Linseed, boiled, bbl., 62c; cs., 67c; raw, bbl., 60c; cs., 65c; Lucol oil, boiled, bbl., 53c; cs., 58c; raw-bhl., 51c; cs., 56c. Kerosene—Pearl, per gal., 18c; As; tral, 18c; Star, 18c; Extra Star, 21c; Eocene, 20c; Elaine, 26c; Water White, in bulk, 11<sup>1</sup>/<sub>2</sub>c; Mineral Seal iron bbls., 18c; wooden bbls., 20<sup>1</sup>/<sub>2</sub>c; cs., 24c; Minera; Sperm, cs., 26<sup>1</sup>/<sub>2</sub>c; Deodorized Stove Gasoline, hulk, 15<sup>1</sup>/<sub>2</sub>c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphta or Benzine, deodorized, in bulk, per gal., 12<sup>1</sup>/<sub>2</sub>c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 65c; cs., 70c; Neats-foot Oil, pure, bbl., 63c; cs., 68c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; W bale Oil, cs., 53@68c.

BORAX.—Concentrated, 6@7c <sup>1</sup>/<sub>2</sub> lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c <sup>1</sup>/<sub>2</sub> lb.; No. 1, 4@5c. LITHARGE.—Pure, in 25-lb. bags, 8@9c <sup>1</sup>/<sub>2</sub> lb.

MOLYBDENUM.—Best, \$2.75 <sup>1</sup>/<sub>2</sub> lb.

CHROMIUM.—90% and over, <sup>1</sup>/<sub>2</sub> lb., 80c.

PHOSPHORUS.—American, <sup>1</sup>/<sub>2</sub> lb., 70c.

SODIUM.—Metal, <sup>1</sup>/<sub>2</sub> lb., 50c.

BISMUTH.—Subnitrate, <sup>1</sup>/<sub>2</sub> lb., \$2.10.

URANIUM.—Oxide, <sup>1</sup>/<sub>2</sub> lb., \$3.50.

MERCURY.—Bichloride, <sup>1</sup>/<sub>2</sub> lb., 77c.

TUNGSTEN.—Best, <sup>1</sup>/<sub>2</sub> lb., \$1.25.

SILVER.—Chloride, <sup>1</sup>/<sub>2</sub> oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, <sup>1</sup>/<sub>2</sub> lb. 7c; less than 500 lbs., 7<sup>1</sup>/<sub>2</sub>c.

MANGANESE.—Black oxide, <sup>1</sup>/<sub>2</sub> lb., 2<sup>1</sup>/<sub>2</sub>@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads <sup>1</sup>/<sub>2</sub> 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, <sup>1</sup>/<sub>2</sub> ton 2000 lbs. in 125-lb. hags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MAY 16, 1905.

790,018.—GAS ENGINE—G. A. Aldrich, San Francisco.  
790,019.—FLUID MOTOR—G. A. Aldrich, San Francisco.  
790,022.—ROASTING ORES—Anker, Watson & Evans, Los Angeles, Cal.  
789,784.—VEHICLE—C. P. Balch, Dufur, Or.  
789,808.—FRUIT PITTER—J. S. Briggs, Los Angeles, Cal.  
790,027.—SQUARE—L. Brodt, Berkeley, Cal.  
790,029.—HARP—J. P. Childs, Spokane, Wash.  
790,035.—TREATING MOLASSES—F. Deusy, San Francisco.  
790,036.—REFINING SUGAR—F. Deusy, San Francisco.  
790,117.—VISE—K. L. Erickson, Park, Wash.  
789,849.—COAL FEEDER—G. W. Gardner, San Francisco.  
790,120.—NEEDLE—D. E. Garrett, Berkeley, Cal.  
790,046.—CAISSON AND TUNNEL—P. J. Gilden, San Francisco.  
789,852.—RAVELING MACHINE—O. C. N. Gunderson, Spokane, Wash.  
789,973.—CUT OFF SAW—C. A. Hartman, Hoquiam, Wash.  
789,789.—HEATING LIQUID FUEL—F. W. Jackson, Needles, Cal.  
790,021.—GAS ENGINE—N. L. Rigby, Garvanza, Cal.  
790,117.—VISE—K. L. Erickson, Park, Wash.  
789,980.—TIRE SHIELD—J. Marsden, San Francisco.  
789,926.—FLUSHING DEVICE—F. H. Mason, Spokane, Wash.  
789,995.—WHEEL—D. C. McCan, Nordhoff, Cal.  
789,929.—LATCH—E. North, Los Angeles, Cal.  
789,874.—REVOLVING TRACK—H. N. Owen, San Francisco.  
789,881.—PRINTING PRESS—P. F. Rice, Tustin, Cal.  
790,078.—VIBRATOR—N. L. Rigby, Garvanza, Cal.  
790,158.—SWITCH—W. H. Sammons, North Bend, Or.  
789,889.—BUTTER CUTTER—E. Sutherland, Los Angeles, Cal.  
790,163.—POCKET TRANSIT—W. D. Verschoyle, Seattle, Wash.  
789,947.—DITCHING MACHINE—M. A. Wheaton, San Francisco.  
790,241.—TELEPHONE MOUTHPIECE—W. Wright, San Francisco.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DITCHING MACHINE.—No. 789,947. May 16, 1905. Milton A. Wheaton, San Francisco, Cal. This invention relates to an improved machine for digging ditches, trenches and the like. Its particular object is to provide a portable machine of this character adapted to operate efficiently in swampy or marshy land, and in soft or clayey or sticky soils, as well as in dry ground, and which may be propelled and operated by its own power. It consists in the combination of a suitably supported hollow cutting device comprising a plurality of circumferentially arranged cutting blades directing material into the interior of the cutter, means for moving it on lines transverse to its axis of rotation and conveyer means operating with the cutter.

PNEUMATIC TIRE SHIELD.—No. 789,986. May 16, 1905. Joseph Marsden, San Francisco, Cal. This invention relates to means for protecting pneumatic tires from puncture and at the same time maintaining the resiliency of such tires under the varying pressure of loads and shocks. The object of the invention is to provide a protecting envelope or casing surrounding that portion of the tire which is subject to puncture or abrasion, and to so connect the free edges of the casing with supporting parts that the casing itself will partake of the compressions and extensions of the inclosed tire under loads, and thus allow the air within the latter to exercise its full resilient action under compression and expansion. It consists of a shoe inclosing the outer periphery of the tire having its edges free, springs having the outer ends connected with said edges at intervals, swiveled attachments for the inner ends of said springs, and means for securing said attachments to the wheel spokes.

SEPARABLE SQUARE.—No. 790,027. May 16, 1905. Lincoln Brodt, Berkeley, Cal. The object of this invention is to provide a square which shall have its branches separable one from the other to allow it to be packed or carried in a small compass, and which shall be simple in construction and thoroughly practical in operation. The device comprises two separable members, one of which is grooved and the other provided with a corresponding tongue having side and end abutments, said members having a coincident wedge-shaped aperture, a wedge removably fitting said aperture and means for operating the wedge to lock the grooved member in contact with the abutments of the tongue member.

PROCESS OF TREATING MOLASSES.—No. 790,035. May 16, 1905. Felix Deusy, San Francisco, Cal. The object of the present invention is to produce a comparatively high minimum density, and consequently a high osmose in the molasses during the osmose period, and thereby effect at a single operation the elimination of a larger quantity of salts than is possible under ordinary methods and with ordinary apparatus, increase the yield of sugar in the osmose molasses, and decrease the quantity of sugar lost in the exosmose liquid. It consists in a process of flowing the initial molasses and the osmosing-water in opposite directions to cause one to pass the other, and adding to the liquid undergoing osmose a part of said liquid which has already been osmose and concentrated.

## Life on the Yukon.

With each return of the summer season the interest in mining in Alaska and the Yukon region takes on new life. It is then that the venturesome spirits—such as those who have opened up that land of ice and snow and made life endurable there—turn their faces in that direction in search of fortune. It is owing to this spirit that every vessel from now on going northward from the Pacific States to Alaskan ports will be crowded with passengers and freight. Since the discovery of the rich gold deposits in the Yukon basin numerous towns have come into existence and many thousands of people now winter in the Far North, but little removed from the Arctic circle. Dawson, Forty-Mile, Eagle, Rampart and Fairbanks are all within 100 to 200 miles of the circle, and Fort Yukon is directly on the Arctic circle, at the most northerly point reached by the Yukon river. From there it flows southwesterly into Bering sea. Although the Yukon rises in British territory, only a few tributary streams heading in Alaska, the greater part of the length of the river flows through Alaska—the stream crossing the international boundary at Eagle City. The Tanana also heads in the Yukon Territory, but the greater part of it is in United States possessions.

Mining outside for placer gold is mostly carried on during the months from June to October. Those wintering in the country have, of course, the advantage of an early start, as transportation is not open until after mining operations are possible in the interior. During winter the miners work in their claims, drifting out the frozen ground by the use of "steam points." These are pipes drawn to a point and perforated with small holes. The pipes are driven into the gravel and steam turned in from a boiler located on the surface. Many schemes for thawing the frozen ground have been tried, but the steam point has proven the most economical and satisfactory. The gravel, softened by the steam, is sent to the surface and dumped. In this manner large piles of gold-bearing gravel are accumulated, to be washed the following summer when water is available.

The accompanying engravings will give a good idea of the life of a miner on the rivers. During winter the streams are frozen solidly to a considerable depth and some of them to the bottom. Traveling on the ice by means of sleds drawn by horses or dogs is the usual method of moving about and is the least expensive means of transporting freight of any description. As summer approaches the snows soften, the ice becomes slushy and for a time travel is practically at a standstill. Soon, however, the warmth of the sun, which increases with the growing length of the days, causes the streams to flow. The

Traveling on the Ice on the Yukon.

Preparing to Go Down the River on Breaking Up of the Ice on the Yukon.

ice breaks up and floats away. Often at some point, usually at a bend in the river, the ice forms a jam and the floating ice from up the river, continuing to come down, increases the obstruction rapidly, causing the water to back up over a considerable area, until it either overflows the barrier of ice and carries it away or cuts for itself a new channel across the low flats adjacent to the river. This is reported to have happened within a month near the town of Fairbanks. The details of this incident have not yet reached the outside world. When the rivers

are free from ice the prospectors can go up or down the stream in boats or canoes, and those desiring to go up stream often improvise a vessel in the form of a small raft, which they "pole" or paddle in the direction they wish to go. One of the engravings shows two men thus sailing in their ship of fortune. Another gives a view of several larger rafts and scows, some of which are covered with tents or tarpaulins as a protection against the changeable weather. They are waiting for a clear river. A fourth view shows one of the larger scows.

**A** LACK of water in the new district of Goldfield, Nev., is interfering seriously with the plans of milling ores in the district. The water is obtained from comparatively shallow shafts, and there is little doubt the water supply will be increased by sinking deeper. When water is obtained so close to the surface it is usually found in increasingly greater amount in depth. Water has been found in this district unusually close to the surface for the desert region—65 to 205 feet. If water is not obtainable in sufficient amount from the neighboring mines, it is safe to say that the energy and enterprise of the mine owners of that camp will provide water from some more distant source.

**Z**INC tailings are proving a source to wealth of the mines of the Barrier range, in New South Wales, the Broken Hill Proprietary mines having demonstrated that the long despised zinc ores which occur so abundantly at Broken Hill can be treated successfully and that company is making a commercial success of their treatment. The British Broken Hill Company now fall in line and are constructing a plant on lines similar to that of the Proprietary Company and will treat their tailings, over 300,000 tons of which have accumulated there. The former company had been using these tailings to fill mine stopes, and this filling they now intend to attempt to withdraw—with what success remains to be seen. It is stated that the tailings contain about 17% zinc in the form of blende, which will repay the cost of recovering the metal from these ores once they are again on the surface. The mining methods adopted in recovering these tailings will be of interest.

**I**N no section of the country is the leasing system so extensively employed as in Colorado. It has made it possible to profitably work a large number of mines which under corporate management would be failures financially. It is because of the extraordinary expense of corporate management. Under the leasing system everything is done in a matter-of-fact, practical way. There are no "frills" and no high-priced managers; no heavy and unnecessary foreign

office expenses. The success of the leasing system in that State affords much food for thought when contemplating some of the larger corporate enterprises. In at least one instance where a corporation reserves to itself the richest part of its property and works it—at a loss—the poorer portion is given over to leasers, who pay a good royalty and make a handsome profit for themselves. Further comment on the two systems of mine operation seems unnecessary.

## Penalty for Misrepresentation.

In England, as well as in the United States, much attention is given by the investing public to the capacity of a mining concern to earn dividends on a stated capital, the same as if it were a railroad or a manufacturing enterprise. Indeed, to such an extent is this fallacious idea carried out by promoters and others that mines are not infrequently spoken of in glowing terms as "manufacturing enterprises"—great industries where gold, or copper, or some other metal is manufactured. A moment's thought will indicate how unsound such reasoning is. A manufacturing enterprise may endure and increase its volume of output for years, and even for generations, for there are many such enterprises founded several generations back that are still in successful operation, engaged in manufacturing—where the raw materials of one season's operations are replaced the next with new, and the industry continues to thrive and expand throughout a long period of years. Its only limitations are the ambition of the management and the ability and willingness of the market to absorb what is thus produced.

In these lines there is always severe competition, and this, together with the limitations of the consumption, are practically the only restraints placed on the expansion of a manufacturing enterprise. With mining it is entirely different. Its possibilities, however great, are really limited by the amount of ore actually available and which may be extracted and the values recovered at a profit. There are mines which have been successfully operated for centuries, producing in the aggregate millions in value. The tin and copper mines of England are instances. Then there are mines which within a score of years of their discovery have produced more value than all the tin and copper mines of Cornwall throughout their entire history of centuries of active operation. The Comstock furnishes numerous examples of this latter class. There is a third class—great mines, not inexhaustible by any means, but long-lived, profitable and looked upon as among the safest of industrial investments, which they undoubtedly are. The Homestake, Alaska-Treadwell, Mount Morgan, Broken Hill and other similar great mining enterprises are excellent examples of this class. The famed copper mines of Lake Superior are in still another class. They have been profitably worked for many years, and some of them promise to continue for many years to come. Few mines in the world have on the whole made so large profits from original investment. The Calumet & Hecla leads the world in this regard. On a capitalization of \$2,500,000 this company has disbursed in dividends exceeding \$85,000,000.

This brings the proposition fairly before us. What actual relation does capitalization of a mining corporation bear to its real value? In most cases, it may be safely said "none at all." In contradistinction to the career of Calumet & Hecla may be taken any one of a score of properties capitalized at figures ranging from \$1,000,000 to \$20,000,000 that have never paid a dividend and never will, because they do not possess the elements essential to a dividend-paying proposition. It must be acknowledged that, in fact, a mine only is capable of producing what may be contained within it—the ore actually existing within the entire limits of the property, whether this may be recovered at a profit or not. If the mine is a dividend payer, the question naturally arises, "how long will the dividends continue and in what amount?" Upon this basis—the real possibilities of the mine—should the valuation be made, and not upon its ability to keep up these dividends indefinitely. A mine may be able to pay \$25,000 per month with a 40-stamp mill. This is \$300,000 per annum—6% on \$5,000,000. If the mill capacity be enlarged to eighty stamps, it is reasonable to assume that the dividends will be increased to \$50,000 per

month. Does this make the property worth \$10,000,000? Some argue that it does for the reason that it is 6% on \$10,000,000. The fact may be that the mine may never be able to pay dividends longer than five years with a 40-stamp mill, or \$1,500,000 net, instead of \$5,000,000. This in no manner detracts from the real value of the mine. The mine itself, under proper management, will pay just as much in dividends with a capitalization of \$100,000 as it will if capitalized at \$20,000,000.

It is due to a lack of knowledge on the part of the investing public in mining affairs, practical and technical, that unscrupulous promoters and others are enabled to take an unfair advantage of the people. Prospectuses and annual official reports teem with misleading and untruthful statements, but the public, being unfamiliar with the business of mining, are not discriminating, and invest in enterprises having no real merit or pay too much for stocks in those which have actual value and are dividend payers.

In England the Government has undertaken to protect the investor by passing a law making certain misstatements concerning a mining company's financial affairs criminal. Two amendments have recently been made to the existing law, as follows:

1. If any person, being a director, manager, secretary, or other officer of any company, or being the auditor of the company, whether an officer or not, wilfully circulates, publishes, or makes or prepares for circulation or publication, or concurs in so circulating, publishing, making or preparing any written statement or account relating to the financial affairs or property of the company which he knows to be false in any material particular, he shall be guilty of a misdemeanor, and shall be liable on conviction on indictment, to imprisonment, for a term not exceeding two years, or in the discretion of the court, to a fine not exceeding £500.

2. For the purpose of this section the expression "company" includes any company formed for the purpose of gain and incorporated by charter, or by or under any Act of Parliament, and any friendly society, whether registered or unregistered, and also any society or body of persons (or other than a friendly society) which is registered by or with the Registrar of Friendly Societies, under any Act of Parliament.

This new Act will be known as the "False Statements (companies) Act."

If the law were extended to include untruthful statements concerning the actual value of the property it would be more complete. There seems to be as much need of a law framed along these lines in America as there has been in England. Mines cannot be developed without money, and the spirit of speculation which is naturally in the people makes some of these undeveloped mining propositions attractive, but the facts should be told concerning the property, not falsehoods. Then if the public loses on a "flyer," they have nothing but their own cupid-ity to blame.

## A Caved Mine.

The recent disastrous cave reported as occurring in the United Verde mine workings, at Jerome, Ariz., illustrates in a forcible manner the short-sighted policy of "cheap" extraction of large bodies of ore, even if in hard rock, without filling. There are many large mines where the good-standing qualities of the ore and wall rocks lead the management to adopt a system of mining which must ultimately result in disaster. The removal of hundreds of thousands of tons of ore from a large vein or deposit, and the attempt to support the walls and overhead ore by means of timber must have a limit even in the best standing ground. It might be permissible for a single stope to be excavated, and the roof and walls supported by a system of timbering without filling. When a series of stopes, one above another, are thus opened, with only shell-like intervals of rock between levels, an element of danger is introduced which should be avoided, but having been created should receive prompt and proper attention, or, as in the case of the United Verde, the ultimate cost may perhaps exceed that of the application of the proper methods in the first place. It is simply another object lesson in mining, teaching the observer how mining should not be done. As a result of this short-sighted policy the United Verde mine is practically closed. The buildings are settling, and it is said the shafts and foundations of the hoists are so much out of line that no hoisting can be done, and it may be several weeks, if not months, before active work can be resumed.

## CONCENTRATES.

"HIGH-GRADING" is a term recently come into use in Colorado to signify the theft of high-grade ore.

UNDERHAND STOPING is only advisable on small and unusually rich veins. It is not commonly practiced in the United States.

CHARCOAL is used to precipitate gold from chloride solutions at the reduction works of the Mount Morgan mine, Queensland, Australia.

WHERE a contract is signed by only a portion of the owners of a mine, the Supreme Court of California has decided that such a contract is not binding.

ARKOSE ROCKS are those formed from the disintegration of granites. They are fragmental rocks, but in composition resemble the granite from which they are derived.

MANGANESE usually occurs as black oxide in several minerals, notably pyrolusite and psilomelane. The carbonate and silicate are also abundant in same localities, but the sulphide alabanite is rare.

"GRUB-STAKE CONTRACTS" need not necessarily be reduced to writing, as they do not come within the statute of frauds. The grub-stake contract is similar to what is legally termed "qualified partnership."

THE Sierra Pintada placer mines are in Lower California. They were discovered in 1899 and a small stampede followed, but, as pointed out in these columns at that time, the extent and value of these diggings were greatly overstated.

THE Yellow Jacket shaft was the first deep vertical shaft sunk at the Gold Hill end of the Comstock Lode, Nevada. It was several thousand feet east of the shafts in the town of Gold Hill. Since that shaft was sunk the Forman and Combination were sunk far east of the line of the Yellow Jacket shaft.

TO PROPERLY SUPPORT the soft walls of a vein after stoping where no filling is cheaply available, heavy plates (3-inch plank) should be placed between the timber and the wall. If this method does not afford sufficient support, posts must be used as well as stulls, thus forming a sort of square-set system.

IGNEOUS rocks, originally hard and flinty, sometimes become softened by decomposition of the feldspars. The so-called "white porphyry" of Leadville, Colo., is of this character. This rock was originally a hard dense quartz porphyry. It is now comparatively soft, from the decomposition of the feldspars, which have become kaolinized.

WHEN opening a mine by extensive open pits, if there are underground workings below these pits, provision must be made for their drainage, and the greater the superficial area of the open cuts the more water they will collect and send into the underground workings, unless the necessary provision be made to drain the water away.

FIRE clay is often found beneath coal seams and veins. They are comparatively free from alkaline earths, as these have been largely or wholly removed by pre-existing vegetation. Any substance which has a tendency to render the clay fusible should be sought for, as these render the clay useless for the manufacture of refractory materials.

WHERE large dumps of either waste rock or tailings have to be handled, some expense can be saved by improvising light, portable chutes, up to which the cars can be run and the material scraped or shoveled into it. By a proper arrangement of this kind the cost of handling can be reduced one-third to one-half that of shoveling from the floor.

WHERE porous rock contains a low grade of copper, say about 2%, in the form of carbonate the metal may be recovered by leaching the copper out of the crushed ore by means of a dilute solution of sulphuric acid and precipitating the metal on iron or tin scraps in boxes. The resulting precipitate is an impure copper, which is collected, dried and sacked in canvas bags and shipped to a refinery if no smelting furnace is at hand, in which it may be treated.

IN the matter of alien ownership of property, Nevada law provides that any non-resident alien, person or corporation, except subjects of the Chinese Empire, may take, hold and enjoy any real property (mining claims are real property), or any interest in lands, tenements or hereditaments within the State of Nevada, as fully, freely and upon the same terms and conditions as any resident citizen, person or domestic corporation. The law does not state that a resident Chinese subject may not hold property in Nevada. A Chinese born in the United States is a citizen in the eyes of the law. The question as to the status of the Chinese resident of Nevada, as a part owner of a claim, involves many con-

siderations not within the scope of the mining law. It seems a case for settlement in the courts, as undoubtedly the Chinaman had a right to hold the one-third interest deeded to him by the locator for a consideration—the assessment work.

PLACER MINERS everywhere should carefully save the black sands which are recovered from the sluice boxes at the time of making the cleanup. In many districts these sands are valuable—in some for gold contained, in others for platinum and in others for the rare earth minerals, such as monazite. Systematic and thorough tests of black sands are to be made this year at the Portland, Or., Exposition, and much valuable information will be obtained as to the character of the black sands.

"STINKERS" are charges of nitro powder which burn instead of exploding. The name given by the miners to this sort of occurrence is more descriptively forceful than elegant. They are usually caused by placing the detonating cap too far down in the charge, and, in consequence, the communication of the fire from the interior of the fuse to the powder, which burns, filling the mine workings with obnoxious and deadly gases. "Stinkers" can generally be avoided if the fuse and cap are properly arranged and not placed below the first stick of powder used.

THE railroad extension from the former terminus of the Peruvian railroad at Oroya to the mines at Cerro de Pasco was built primarily to aid in the further development and operation of the old mines at the latter place, which were formerly great producers of silver, but are now being worked for copper by J. B. Haggin & Co. of New York. The road is 82 miles in length. The altitude at Oroya is 12,250 feet and at Cerro de Pasco is 14,200 feet, which is higher than any mining camp in America. The maximum grade is  $2\frac{1}{2}\%$ —about 220 feet to the mile—and the maximum curve  $16^\circ$ . The rails are of 70-pound steel. It is one of the highest railroads in the world.

THE occurrence of an iron cap or gossan is not always a safe indication of the existence of bodies of copper ore beneath, though copper deposits not infrequently have a capping of iron oxide, silica and lime. Some copper vein outcrops contain barely a trace of copper, others are rich in oxides and carbonates. The climatic conditions, and to no small extent, the topography of the country, have a marked influence on the superficial portions of copper veins and deposits. Copper glance does not always intervene between the zone of carbonates and of the normal sulphides below, though this is characteristic of some localities, particularly Butte, Montana.

THE gold-bearing streams of the mountains of California have mostly been worked out long since, at least such portions as would pay by the ordinary methods in use. The gold has been recovered by sluicing; by the use of the hydraulic elevator; by turning aside the streams, sometimes by means of flumes, and occasionally by diverting the water through a tunnel, thus making it possible to drain long stretches of bedrock, and to recover the gold. Dredging has been attempted to a very limited extent in the mountains as the streams are all torrential, and any scheme for working the beds of these rivers must be carried out during the low stage of water, as the freshets of spring usually sweep every obstruction away.

MINING claims in California are located under the Federal law. The annual assessment work must be done as required by the United States Statutes. If a vein outcrops on an agricultural patent, such a vein has no extralateral right. That is, the owner of the land is not permitted by the law to follow the vein downward beyond the side line of the agricultural claim. If a shaft be sunk outside of the patent to reach the vein, the discovery so made, if on unoccupied public land, might be called an apex, for legal purposes, and the courts would no doubt so construe it, admit the validity of such discovery and grant to the discoverer all the privileges to which he would be entitled if the discovery were made on the surface.

CONSIDERABLE experimenting has been done in Canada in the concentration of molybdenite, and a varying degree of success has been attained by the several methods tried. Among these are electro-magnetic separation and some of the several forms of shaking-table concentrating machines. Enough has been done along these lines to show that each particular ore offers a separate proposition in concentration, and until each is tried the result that may be obtained on any given ore is an experiment and separate tests are necessary in each case. Jigs have been tried, but did not give satisfactory results. The ore should preferably be crushed by rock breakers and rolls, stamps being undesirable for this purpose.

THE pressure at the in-take of a syphon per square inch is exactly that of the atmospheric pressure at that place and time. The in-take end does not require to be immersed several feet, but just below the surface of the water—sufficiently to exclude air from the syphon. The principle upon which the syphon operates is this: If both legs of the syphon be filled with water, both ends having been stopped and the shorter leg immersed a

short distance in a body of water, if the stoppers be removed, the water in the longer leg having greater weight than that in the shorter leg begins to flow out. This has a tendency to create a vacuum in the pipe, but this tendency is immediately counteracted by the pressure of the atmosphere on the surface of the reservoir, which will cause a column of water to rise in the pipe equal in weight to the atmosphere present. This at sea level is a column about 33 feet in height, and in the mountains proportionally less as the pressure of the air grows less with increasing altitude. The height to which water will rise in a syphon is always somewhat less than that theoretically calculated due to the pressure of the atmosphere.

MOLYBDENITE may be recognized by the following properties: It occurs in bright metallic scales, brighter than pure graphite; flexible but not elastic; soft, easily soiling the fingers or a paper; when heated gives off sulphur fumes, and before the blowpipe held in the forceps colors the flame yellowish-green; infusible; decomposed by nitric acid, leaving a white or grayish residue. To detect the presence of molybdenum in its ores, pulverize the sample to a fine powder and place in the lid of a platinum crucible resting on a triangle. Add a few drops of concentrated sulphuric acid and stir. Heat, and dense white fumes are given off. Cooling, and breathing on it repeatedly, the vapor becomes a decided and beautiful blue. The blue coloration disappears on reheating, but returns on cooling. If water be added it disappears.

QUARTZITE is a compact, crystalline, granular aggregate of quartz, either in irregular, crystalline grains or in developed crystals. Quartzites are the result of the consolidation of what were originally sandstones. In certain districts the quartzites have been silicified by the infiltration of silica, and there has been a secondary enlargement of the quartz grains by the formation of an envelope of silica about each individual grain. This infiltrated silica has assumed a crystalline form. The polarization microscope shows that each separate grain is enveloped in this foreign silica, and usually the outline of the original grains can be distinctly traced. Sandstones also are sometimes cemented by iron, lime or clay, but these are not, strictly speaking, quartzites—but sandstones. Mica sometimes develops in sandstones and quartzites, giving the rock a schistose appearance.

IN the early years of gold mining in California and for many years thereafter only raw copper plates were used as collectors of amalgam. The silver-plated copper plates were introduced twenty years or more ago. For the best results the plates should receive a heavy coating of silver. The use of pure silver plates has been suggested, but it is unlikely the suggestion will be extensively followed owing to the cost. If the plates are made thin they are likely to bend, which, producing an uneven surface, is unsatisfactory, and if sufficiently heavy to resist warping the plate becomes too expensive. Copper plates which have been properly electro-plated with silver have been found to answer every requirement. If the gold in an ore is readily susceptible of amalgamation the amount of gold in the ore must be small if it will not deposit a substantial film of gold amalgam on the plates.

IN MINING the timbers employed in the various kinds of work have each a distinctive name. Thus, in shaft timbers, the main members adjacent to the walls are called wall plates; those at the end, end plates; the uprights at each corner, and sometimes in intermediate positions, are posts or studdles; the timbers dividing the shaft into two or more compartments are dividers or center braces. In the square-set system, the members lying upon the floor of the level are sills; the upright vertical pieces are posts; the pieces extending in sections between foot and hanging walls are caps; pieces reaching from the hanging wall to the second post from the wall are called butt caps; pieces reaching from a post to the foot wall and lying in a hitch are called cap sills. The members reaching from post to post and lying longitudinally of the vein are ties. Some improperly call them sprags. Pieces extending upward diagonally toward the hanging wall are angle-braces. In narrower stopes, timbers reaching from wall to wall are called stulls. If pieces are put in between the stulls, to make them more rigid, these pieces are called sprags. Sprags are also used in drift sets. They reach from post to post, at the sides of the drift, near the top, and are to overcome a tendency of the sets to "ride." In drift sets, the uprights are posts, the pieces extending across the drift from post to post are caps. Pieces placed above the caps, and separated from them by wedge-shaped blocks, are called bridges, and are to facilitate in driving the narrow strips overhead called lagging. A piece reaching across the drift and extending beneath the posts is a sill. In addition to the above, there are hanging-wall plates, foot-wall plates and props (usually specially placed.) In shafts there are also skids for tracks and guides for cages and skips, and in some shafts at stated intervals heavy timber called reachers are placed, the ends of which rest on hitches cut in the rocks. The function of these timbers is to take the weight of the timbers in the shaft, or at least to render them more secure. There are few full shaft sets that weigh less than 2000 pounds per set, and many weigh much more than this. The reachers take the weight in case the wedges become displaced or shifted and thus render the shaft more secure.

## Thirty Days of a Mining Engineer's Life in Mexico.

Written for the MINING AND SCIENTIFIC PRESS by  
E. A. H. TAYS.

Upon returning from a trip into southern Mexico I found a letter requesting a report on a certain United States company's mines in the State of Durango, near the city. The letter stated: "Our mines are but twelve hours ride from the city and two days from Mazatlan," and the parties advised me to go via Mazatlan, as they were in a hurry for the report.

Mazatlan happens to be seven days hard riding from Durango, under auspicious circumstances, and as the season was a bad one, and as no steamer was due at my nearest port for several days, I decided that "the long way round was the shortest way—," and took the stage north to Guaymas, going around via Benson, Arizona, and El Paso, Texas, calculating to reach Durango in seven or eight days; but our calculations often fail.

I left Fuerte, Sinaloa, on the evening of March 6th, taking the stage for Alamos, Sonora, a night's ride. As the river had been "up" for over a month, the stage could not cross, so passengers and mail had to cross the river in a canoe. I secured my ticket and took myself and baggage—consisting of a roll of bedding and a camp cot, a telescope valise and a canvas bag containing my saddle—down to the river early, and crossed over nearly an hour before the stage started. At the river bank the man in charge of the boat informed me that no charge was made for stage passengers, but if the passenger desired to "tip" the boatman, there was no objection. He was fairly well "boozed" up and, after imparting the above information, "struck" me for a dime. I produced the dime and he started up the bank for the town. Fearing he might delay, I induced him to ferry me across at once, which proved to be a good move on my part.

Once across, I sat on my baggage for about an hour waiting for the stage to come down for its load. In due time it came, and in the meantime, on the opposite bank of the river, had gradually collected rather a heterogeneous load for the canoe. Besides some eight or ten sacks of mail were six men, two boys, two pack saddles and other things; and, on either side, held by ropes, swam two burros. Some difficulty was had at the start, but finally boat and burros started together and, the stream being swift, and three of the men rather drunk, several times it looked as though the craft would capsize, and I congratulated myself on being on shore, and on the "safe" side.

The canoe finally landed a couple of hundred yards below where we were, so I was loaded into the stage and we drove down and secured the balance of our load.

The stages on the west coast of Mexico are of the

lady passenger inside, where she stayed until put down at a little house on the outskirts of Alamos, where we arrived about 7 A. M. of the 7th.

At the stage office I hired two men to take my baggage over to the Yaqui River stage line office and arranged for my passage at once. As they allow only twenty-five pounds of baggage, I had to pay \$10.80 for the 150 pounds of extra weight. I found the stage left at 12, so went to a nearby hotel and went to bed, sleeping for about two and one-half hours.

Feeling somewhat refreshed after my sleep, I attended to some business, and about 11 o'clock had something to eat, as I was hungry, having eaten nothing since the day before at one of the stage stations.

At 12 sharp we left Alamos, making Navojoa, on

Works at La Teresa Mine, Sinaloa, Mexico.

light, sweet bread handed it to the tramp, with the remark: "If you are hungry, eat this. I gave you a half dollar the other night and saw what you did with it, and will give you no more money." The fellow, taken by surprise, took the bread with profuse thanks and took a bite of it, but he had not taken his outraged stomach into account, for, after making a few chews, he turned around suddenly and spat it out in evident disgust. At this we each gave the fellow a dime and told him to go off and get a drink. Such is life!

It had been threatening rain all day and early that night it turned loose in earnest; and, no stage from the north arriving, we were obliged to wait. It rained all day and all the next night. About midnight the northern stage arrived and was to return at 9 A. M. My newspaper friend remained for a more propitious time, but an agent of the Singer Sewing Machine Co., a Mexican, and I decided we would go.

The Mayo river was up and rising rapidly. Of course the stage could not cross, so the mail (some ten sacks) and we had to cross in a canoe. This proved to be a good one, handled by two stalwart Mayo Indians.

We walked to the river in the mud and rain, while a native took our baggage in a wheelbarrow. At the river the stage driver yelled across to tell the passengers that the roof of the wagon (the stage had been replaced by a light Studebaker wagon with a canvas top) leaked and for them not to come. The passengers, however, had decided to take their medicine and went. We sat in the open boat in the rain while being ferried across and were glad to get under the canvas cover, which we found did not leak.

The wagon had but scant room, and after all the mail sacks and our baggage had been stowed away, there was small space for the two passengers, and knees and heads were close together. It was well that our newspaper friend stayed behind, for the wagon would not hold a peck measure more.

We started in a pouring rain, with mud 6 inches deep everywhere.

By 2 P. M. we made the first relay station and at 6 P. M. the second, where we stayed over night, sleeping under an open porch and making a supper of beef tamales, straight.

I had taken the precaution to lay in a basket of provisions before starting, so we ran no risk of going hungry.

The next day we made an early start, reaching Cocorit, on the Yaqui river, and a military post, at about 10 A. M. Here my "Singer" friend left me but another passenger, a young ranchman, took his place; and, to add to our comfort, the agent gave passage to a man, his wife, and a small boy, all of whom had to perch themselves on the baggage between the two seats. It can be imagined we were comfortable.

From Cocorit down the Yaqui river the roads were in better condition and we made good time in spite of our load to Chunampaco, a fort on the river where the road crossed it and where the Government has a

Pack Train Leaving Rosario for La Teresa Mines.

Entrance to La Teresa Mine, Sinaloa, Mexico.

heavy Concord type with seats for nine persons inside, but, as mail and other freight is profitable, it is given the preference; and, once loaded, the passenger piles himself away as best he can, often finding no room for his feet.

After much fussing we started, and I found that a young Mexican, bound for Alamos, was my only companion; and by maneuvering properly we managed to locate ourselves decently.

A few miles out we took on another passenger, a lady, who took her seat with the drivers.

My companion proved to be an employee of one of the city offices and seemed to think that the proper way to put in the night was drinking mescal and smoking cigars. Perhaps he was right; for by midnight the mescal had made him oblivious to knocks and jolts while I remained awake all night.

The roads are, as a rule, rough and unkept, and as the stage is driven at a good speed the passenger gets his money's worth, often getting seasick from the continued rocking and bouncing of the coach.

About daylight it started to rain, which drove the

the Mayo river, a distance of 40 miles, in five hours, changing mules but once.

We had been making good time, but for the next few days "time" was to be counted as nothing. At Navojoa I found that the heavy rains, unusual at this season of the year, had made the Yaqui country a veritable bog hole, and that a stock of good humor and patience would be needed to carry one through. I found at the Navojoa station an old gentleman—a correspondent for some United States newspapers—who proved to be very companionable.

While sitting on the porch that night a rough looking American stepped up to me and said:

"Brother, I am a miner and broke; can't you help me out." He looked very dissipated, and as I had heard the stage "boys" speaking of a Gringo who had been lying around drunk for several days, I remarked: "My man, I have heard of you, and if you are hungry I will give you a meal, but I can't give you money to carouse on." "I would like a meal very much," he said, whereupon my companion stepped into his room and getting a round cake of

cable ferry, which we reached at 4 P. M.

Just as we arrived, and before we could embark on the ferry, it started raining and poured for over an hour. After it cleared up we crossed and drove on to Forrin, the military headquarters of the Yaqui, reaching there at dusk.

Here we found that the water was backing up from the river into a meadow back of the town, threatening to cut off our progress the next day. We also found we would have to lay over a day or leave in a light, uncovered wagon. The young rancher and I decided to "move on," and made arrangements to go on the wagon. We were called at 3 A. M. and were ready to start by 4. As we were about to start I noticed that my baggage was not on and, upon enquiring why it was not loaded, was told it would have to await the next trip. In the next few minutes I did some very forceful and "persuasive" talking, with the result that my baggage was piled up behind our seat and lashed on.

It was still dark when we started, and a few minutes drive brought us to the back water. The driver

sent his "sota" (whip helper) to wade out and sound the way, and while he (the sota) was away, went himself to invest a quarter I had given him in a bottle of mescal—"oil," he called it.

Shortly the sota returned, reporting that he had gone as far as the fence and that there was no way of crossing, as the water was too deep.

The driver, having imbibed "spirit," jumped off the seat and went himself, returning in about twenty minutes and reporting that we could cross.

Our sota had not even gone into the water. We started, it still being dark, and as we reached the water two men seemed to rise out of the ground. One climbed on our load behind our seat and the other took the reins. The driver put a rope through the bit-rings of the leaders' bridles to lead them, and the sota walked alongside to yell and whip.

All went well for a hundred yards, when the water rose to the wagon box and the mules began to bog. For several minutes it looked as though we were going to stick, but yelling, lashing and good luck pulled us over the bad place and we pulled out, the mules all but swimming for fully 25 yards. When we got into the main road we found that our friends were driver's passengers, and they went with us to the outskirts of Potam, the next post and stage station. From Potam we traveled over the open, flat, coast country, over a fairly good road, as here it had not rained the day before, and reached Pitahaya, an isolated post, guarding that section from the Indian raids. Here we found a party of engineers who were at work, under escort, on the survey of a railroad line from Guaymas to and up the Yaqui river. Changing mules at Pitahaya, we struck off across the country for Guacimas, one of the largest military posts in the Yaqui country. The roads were extremely bad in places, and several times we stuck in the mud. Although scouting parties are continually catching Yaquis in this section, the road is well traveled and we continually met small outfits—traders who go from post to post. We met two carts, one drawn by three burros abreast and the other by a mule and a horse, stuck in the mud, and had to lend them a helping hand. The carts were loaded with oranges from Guaymas, and the two drivers were alone. Not 500 yards up the road and about 100 yards to one side, in the brush, we saw two Indians hanging to a small tree, left there four days before by a scouting party that had captured them in the nearby hills to the east. But "dead Indians are good Indians," so they say.

We reached Guacimas just at dusk but could find no place to stay for the night. Our wagon stopped on the roadside in front of the corral where the mules were kept. We succeeded in getting something to eat and then had to sit on the wagon or walk around until 10 P. M. waiting for a small saloon to close, so we could make our beds under the narrow porch. Luckily it did not rain.

The next day we started off at daylight, but had not gone far before our woes began.

We had but two stations to run to make the railroad and calculated to be able to make it by train time, 5 P. M. By 10 A. M. it became evident that the team we had—mules—would not make the first station, so, being near a ranch, we (the two passengers) bought some fodder and fed the mules, giving them nearly an hour's rest. We then hitched up and made a new start, but did not get far before we were stuck in the mud again; but we were not the only ones—there were others. We wallowed along until 1 P. M., when we found ourselves mired and the mules "played out." In this fix we appealed to a nearby rancher, who (it being the Federal mail) sent us two new mules, but, as we had to leave two of our dispirited animals that would not pull, we stayed where we were.

Seeing that further delay meant one more day lost, and perhaps two, I arranged with the mayordomo of the ranch for a two-wheel cart with two mules hitched abreast to take myself and belongings to the Batomotal station. After due delay the rig drove up and an Indian packed me over to a small island, 10 feet square, of dry ground—coming within an ace of falling flat with me enroute. Next my baggage came. The mayordomo was sitting cross-legged in the saddle, at the edge of the island, when my bed was "flopped" down by the Indian. At this his horse jumped, plunged into the mud and started into bucking. The rider managed to hold on for a few jumps, but he was taken at too great a disadvantage, and in one of the lunges, shot out sideways from the horse, measuring his length in the mud—face down. He was a ridiculous sight as he stood up, but he good naturedly joined in the general laugh at his own expense.

As I had but scant time to get to the railroad, counting on further accidents, (according to the Mexican saying, "Blessed are the evils that come singly,") I bade my companions goodbye and started off with an Indian youth for a driver.

We made good time and finally reached the railroad station, with an hour to spare.

The station was closed, and inquiry disclosed that the agent was at a dance given at a ranch, 5 miles away. As I was dirty and bespattered with mud, I repaired to a nearby hut and put on a clean shirt and stiff collar.

It looked for a while as if the train would arrive before the agent, but he finally came, just five min-

utes before train time, so I secured my ticket to Nogales and got my baggage checked just in time. After helping the agent to stow my baggage into the car, I boarded the Pullman and, after we got under way, put myself into the hands of the porter for a general cleaning. When he finished the change must have been great, for the porter remarked as he gave me the finishing touches: "You are quite presentable now, sir."

The next morning (4 A. M.) when we reached Nogales it was raining—had been for two days. The porter called me just as we arrived and I had to hurry, as we only had half an hour. As I was leaving the car the way was blocked by the bringing in of a man with a broken leg, which delayed me. I secured two men, got my baggage from the Mexican side, bought my ticket and opened up my baggage for inspection of the United States officials while the agent made out my checks. I paid no attention to the scolding the customs officials gave me for being behind, but strapped up, with the aid of my men, and managed to get on the train as it was moving out. We arrived at Benson without mishap or delay and got a good breakfast there.

We found that the Overland Limited was five hours late but would arrive in forty minutes, and that the other train was held the other side of a washout, somewhere east of Los Angeles.

Our train arriving, we boarded it, reaching El Paso, Texas, about 10 P. M.—in many places having made but 10 miles per hour, due to the soft condition of the track.

The next morning I crossed the river and sent some telegrams, returning to secure my tickets to Torreon and boarded the Mexican Central train in time. We were detained in Juarez about an hour passing the customs inspection. My baggage inspected again and checked, I returned to the Pullman and settled myself for a comfortable twenty-four hours, relaxing, with a sense of ease, the strain of alertness under which I had been for eight days. It was raining when we left El Paso and it kept it up almost to Chihuahua.

During the night we lost an hour and, as the International makes connection with the Central at Torreon on thirty minutes leeway, I missed the Durango train and had to remain over a day there—a day I spent to advantage, under the guidance of an esteemed friend.

The next day, March 17th, I took the Durango train, arriving at that city at 5 P. M. (ten and one-half days from the start), having lost four days on the trip. I completed arrangements that same night and the next morning at 7 started for the mines, 50 miles to the southeast of the city, in a coach, arriving there at 6 P. M. that same day. The next few days were spent in the usual routine work connected with the acquiring of data for a report on a mining property.

On the morning of March 20th the whole country was covered with about  $\frac{1}{2}$  inch of snow—and this in sunny Mexico at 24° north latitude, but the altitude was about 7000 feet above sea level.

Having secured my data and samples, I returned to the city of Durango and there wrote my report, turning it in on the 27th.

Durango is a city of about 40,000 inhabitants and situated on the western edge of the central Mexican plateau, and about 6000 feet above sea level. At present it is quite a lively place and the number of Americans at the hotels is noticeable. Here, in the Richelieu, is found one of the best hotels in all Mexico. The climate of Durango is delightful all the year round and extremely healthful.

On the 29th I took the morning train north to Tepehuanes, the present terminus of this branch of the International. The road runs as far as Chinacates, along valleys skirted by mountain ranges; but between Chinacates and Santiago Papasquero the route is scenic in the extreme, and is a credit to the engineer who located it. At Santiago it comes out into a narrow valley and follows up the river bottom to Tepehuanes, a distance of about 40 miles.

We arrived at Tepehuanes about 6 P. M. and were driven across the river into the town, where we found very good accommodations at a hotel run by an American. The weather for several days was simply perfection.

That same evening I arranged for mules and a "mozo" (servant and guide), to take me across the Sierras to Culiacan in the State of Sinaloa.

I laid in a goodly supply of provisions in the shape of bread, freshly dried beef, canned fruits, butter, cheese, etc., and the next morning at 8:30 left the town.

For an hour we traveled up the river valley to a little town called La Boca, leaving the river a short way above to climb the first range. As we started up the first slope my mozo stopped, took off his shoes, hid them in the bush and put on his "huaraches" (sandals), with the remark that he would not need the shoes until he returned, as the sandals were better. About 1 P. M. we rode down into a well watered valley, where we stopped to rest and feed. Late in the afternoon it clouded up, threatening rain, and at 5 P. M., arriving at a small ranch called "Chama-cueros," consisting of three log huts in a row, we decided to pass the night there.

(TO BE CONTINUED.)

## Cost of Mine Equipment.

Mining engineers are well aware that to sink a shaft, either vertical or inclined, to a greater depth than 2000 feet is an expensive undertaking, and the expense of equipment increases rapidly when depths greater than 2000 feet are attempted. In the Lake Superior copper region are the deepest vertical and also some of the deepest inclined shafts in the world. On the Rand in South Africa are many deep shafts and deeper ones are in contemplation or already under way. Some interesting figures have been given by a writer in the South African Mines on the cost of some of these deep-level shafts on the Rand. The writer says:

Few adequately realize the colossal expenditures mining companies have to bear before they can enter on the desire of their inception—that of profitable production on a basis commensurate with their scope and possibilities. To state the case roughly, it may be said that a Rand deep level—"1905 pattern"—costs a million sterling before a single ounce of gold can be obtained from it. We have taken four typical up-to-date companies which have entered the crushing arena during the last few months. Of these, one company is an outcrop concern, two are deep levels, and one is a deep-deep mine.

The principal items of expenditure incurred during the "nursery" stage are exhibited below:

	New Klein- fontein. 299 claims.	Robinson Cent. Deep. 456 claims.	Village Deep. 186 claims.	Wit Deep. 285 claims.
	200 Stamps.	100 stamps and Tube Mills.	180-300 Stamps.	200 Stamps.
Property .....	£256,816	£300,000	£ 287,694	£ 299,504
Shafts .....	78,207	63,689	142,963	77,061
Development .....	102,027	34,289	71,961	209,799
Machinery and plant .....	420,480	234,013	568,030	346,211
Buildings .....	57,679	55,428		101,544
Totals .....	£925,209	£687,419	£1,070,638	£1,034,119

It will be noted that in each instance the cost of property is between £250,000 and £300,000. With regard to shafts, the two deep-level hauling ways of the Village Deep make that company's expenditure under this head about double that of the Wit Deep, the property accounting for the next highest charges for shafts. Development costs at the Village Deep for large amount of ore exposed from one shaft are exceptionally small, while the Wit Deep seems to have spent a larger amount of money than one would expect on its ore reserves. The lavish expenditure incurred in present day equipments is ably evidenced in the Village Deep and New Kleinfontein. The plant of the former mine is probably surpassed by no other similar proposition in the world. The Robinson Central Deep has been brought to the producing stage at a much cheaper rate than the other companies dealt with, but its comparatively meager claim area and equipment should be considered in this respect. Taken in the aggregate the expense incurred for the development and equipment of the 715.6 claims mentioned above amounts to £3,717,385, or an average of £5194 per claim.

It must not be thought that the separate items given represent all the heads under which initial expenditure is necessary, or that the totals given are the aggregate sums involved in the operation of bringing the companies to the milling stage. There are numerous other expenses in the way of dues and sundry charges which have not been accounted for in the above. At the same time the table may be taken as a very fair indication of the pre-milling finances of typical mines.

It is interesting to compare the present day position with that existing in the early days. The smaller plants, lesser developments and diminutive ideas of the older outcrops seem ridiculously meager in comparison with the schemes and finances of to-day. For instance, we find in the balance sheet of the Wemmer, February 28, 1905, the following:

To claim account .....	£20,375
Machinery and plant .....	19,526
New battery account (less depreciation) .....	34,024
Cyanide plant (less depreciation) .....	6,850
Mine developments (less redemption) .....	23,800

And so on. Even the prevailing expenses may be regarded as small if we are to discount the vast sums of money that will be necessary for the latest mining conceptions of these fields.

In comparison with the above, some American installations (which cost as much or more than the most expensive of these) have been paid for from the proceeds of mining from the surface. Concerning this very heavy capital expense in the equipment of the deep-level mines of the Rand, an English engineer a short time since said it was considered a matter of small consequence, as the people who subscribed these large sums of money for equipment, development, etc., usually got tired long before the producing stage was reached and would get out of the enterprise at a loss, to try their fortunes in some other venture promising a more prompt return on the investment.

As a fair index of the prosperity of Tonopah, Nev., and of the confidence which its residents have in their district's future, it may be mentioned that 8,000,000 feet of lumber has recently been bought for the construction of new stores and residences.

## The Dry Blower.

Written for the MINING AND SCIENTIFIC PRESS.

In all arid countries where gold is found the dry blower can find employment for his talents. Whether his labors will receive a commensurate reward or not depends upon circumstances—which in this case generally means the richness of his ground. Regions where the dry blower has in the past found—and may again in the future find—profitable employment for the exercise of his ingenuity and labor are found in the great Southwest of the United States, in northern Mexico, in Western Australia, in some parts of Africa, and probably in many other localities. The prerequisites to successful dry blowing are a loose, light soil or gravel, uncemented and containing sufficient gold to make its handling by the slow and laborious—not to say wasteful—processes of dry blowing profitable. Usually dry blowing ground is found in the neighborhood of outcropping veins or zones of gold-bearing rock. Sometimes these outcrops are little, if any, above the desert sands containing the gold, which has been disintegrated from the veins. More dry blowing has been done in Kern county, California, with satisfactory results, than any other place in the Southwest. The district about Red Rock and Goler produced a large amount of gold, the greater part of which was obtained by dry washing and blowing. Machines have been used for years by Mexicans and Indians in the vicinity of the Colorado river, in both California and Arizona, with some success, but these latter diggings never produced the rich results found in Kern county. These led to the discovery of the rich quartz veins in and about Randsburg, though far less gold was

portion of the valley between two of these low ridges there may be a depth of several hundred feet of alluvial material. Often the disintegrated sand, rock and dust are found to be cemented a short distance below the surface, forming a sort of hardpan, and sometimes the hardpan contains nuggets of gold, while usually the stratum immediately above it is rich in coarse and fine gold. Generally the cementing material is lime. The prospector is usually of a curious turn of mind and tests the sands wherever his fancy leads him to do so, regardless of the surroundings, and in not a few instances his efforts have been rewarded by the discovery of payable gold in the wash, where no gold is seen in the rock outcrop. This is probably due to the occurrence of pockets of gold in the vein or in the seams adjacent to it in the country rock. Many pockets are found associated with veins where no gold occurs in the quartz itself.

In these desert regions a constant supply of water for washing by sluicing, or even by rocking, is not available, and as a consequence the prospector must resort to some other means to separate the gold from the alluvial material with which it is associated. This is why dry blowing in its various phases has been introduced in these regions. The simplest form of dry blowing is that practiced by the Indians, and consists in tossing the gold-bearing alluvial in a blanket during a strong wind. The lighter material is blown away, leaving only the coarse rock and gold. The former are picked out by hand and the fine concentrate left on the blanket is then carefully treated by blowing and hand picking until all the gold has been collected. This is also done by passing from one pan to another, as shown in one of the accompanying engravings. Another picture shows the dry blower searching his pan for gold after the winding operation has been completed.

As in many instances good pay resulted from this

one-tenth of the time that a skilled mechanic would require to perform the same amount of work without the aid of such device.

"Piping of steel, iron, brass, copper, or other material can be bent cold up to 2 inches diameter with one man. This device is of value in ship yards, pipe shops, locomotive works and other places where pipe is used to any extent.

"Manufacturers of heating plants, structural and architectural iron, fire escapes, etc., will find this portable pipe bender especially useful; it is also well adapted by having special dies, that can be readily attached, for bending light angles, flats or tee bars to any desired radius as easily as bending pipe. Where pipes are coated by the Sabin process, galvanized, tinned, etc., this machine will bend such pipe to any desired shape without breaking the coating in any way. One man can bend a piece of 2-inch pipe to an S bend in three minutes, no other assistance or device being used or needed."

The Chicago Pneumatic Tool Co., Chicago, Ill., are prepared to handle orders for this device and make prompt deliveries.

## Examination and Valuation of Mines.\*

NUMBER III.

**THE WORK OF SAMPLING.**—First survey the block of ground and plot it on paper to a large scale—say, 2 chains to the inch for areas between 50 and 100 acres, and 1 chain to the inch for areas under 50 acres. Divide the ground on the plan into blocks of 1 to 5 or 6 acres. The shape of the blocks will depend on the surface contours, the direction of the drainage and the probable direction of the gold leads. In some cases the ground is a long narrow strip

Fig. 1.—Concentration by Wind.

Fig. 2.—Looking for Nuggets and Flakes of Gold.

Fig. 3.—The Dry Blowing Machine at Work.

obtained by dry blowing machines at Randsburg than at Red Rock or Goler. In the Cargo Muchacho mountains, San Diego county, California, it is said thousands of dollars were picked up from the surface at a place called Pipindero, and the dry blowers found lucrative employment in working over the sand for finer gold. In many districts in northern Mexico dry blowing is still carried on in a small way, and in New Mexico are said to be good dry diggings, though the term good must necessarily enter a wide range of opinion as to what it may be. What the Indians may call good and be satisfied to work the white man would not waste time on longer than necessary to demonstrate its poverty of resources. In no country, perhaps, has dry blowing been carried on to such an extent as in Western Australia. In some of the gold districts of this section the gold lies on the surface or near it, much the same as it does in the southwestern United States. This occurrence of gold at the surface is due to the climatic conditions peculiar to desert regions. While dry diggings of value may be, and sometimes are, found in gulches in the desert mountains, it is a strange fact that most of the noted dry blowing districts in both America and Australia have been found in a comparatively level country—among low, rolling hills, where the ridges are usually capped by a quartz outcrop, which may or may not be gold-bearing, and the low valleys are filled with the coarse rock and sand, the result of the disintegration of the ridges. The rock masses suffer great and rapid decomposition near the surface, due to the wide range of temperature, and when rain—which is usually rare in these arid regions—does fall it comes almost as a deluge, washing away all the particles of rock which have been sufficiently disintegrated to be moved by the flood. The outcropping quartz veins and surrounding rocks often rise but little above the surface, and probably this is the reason why the discoveries have not been made sooner, as the prospector usually leaves the valley for the hills, where rock exposures are extensive. The desert wash encroaches upon the low rock outcrop, leaving more or less of the rocks exposed to view. As distance from the outcrop is gained the covering of detritus gets thicker, until in the central

very primitive method of working, the inventive faculty of the miner was exercised to find a mechanical device which would effect a separation of gold from sands, making it possible to handle large amounts of material at comparatively little cost. This necessity has resulted in the invention of dry blowing machines and concentrators by the score. Some of these devices are patented, others are not, but all work along the same lines, and their relative merit lies in the readiness with which each machine will screen out the coarse material and separate the gold from the lighter sands and pebbles. Capacity and power required are also important factors. That all the ground susceptible to profit yielding has been worked out, or even all discovered, is very improbable, for in the gold-bearing desert regions finds of auriferous alluvial are likely to be made at any time by the roving prospector. Southern Nevada, southern and western Arizona, southern California, northern Mexico, and the peninsula of Lower California, all offer opportunities in this line, and, as the saying is, "have not been half prospected."

## Pipe Bending Machine.

Herewith is illustrated the Chicago pipe bending

machine. The manufacturers state that an ordinary helper can, with the aid of this machine, bend an amount of pipe to any desired complex curvature in

situated on one or both sides of a river; in others terrace lands in a valley, which are in many cases intersected by lateral streams. Make a mark in the center of each block, and then number the blocks in consecutive order. Proceed to the ground and put a stake or flag in the center of each block. These stakes mark the sites of the sampling holes. The depth of gravel may vary from nothing to 40 feet, or more in very deep ground.

Where the ground is dry and not deep it is customary to sink holes or shafts at the selected points. The whole of the material excavated from the hole is carefully measured in a box of known capacity, washed by cradling, the gold contents weighed and the results recorded.

The record of each hole embraces information on the following points: (a.) Depth of ground. (b.) Character of bottom—that is, whether slate or false bottom. (c.) Character of gravel (note particularly if large boulders or drift timber exist in ground). (d.) Quantity of material excavated in cubic yards, plus 20% (all the boulders, both small and great, must be included in the measurement). (e.) Quantity of gold obtained. (f.) Quantity of gold per cubic yard.

In ground where the sinking of holes would be impeded to any considerable extent by water, it is usual to put down 5-inch or 6-inch boreholes at the selected points. The holes are lined with tubing, and the material extracted by the sand pump collected in a wooden trough, washed, and the gold contents weighed.

Record the depth of the hole, and calculate the cubic contents from the outside diameter of the pipe, plus 20%. The excess is added because experience has shown that the gold values calculated from the displacement of the pipe alone are always higher than the actual returns. This is, no doubt, largely due to the circumstance that a higher extraction or saving of the gold is effected in the sampling tests than in actual practice.

**WRONG METHODS OF SAMPLING.**—The method of selecting the test samples from open faces or from the sides or floor of small streams has often led to er-

\* Prof. Jas. Parks in N. Z. Mines Record.

roneous conclusions. In these places the gold is generally more or less concentrated, thus rendering it impossible for the examiner to form an approximate estimate of the average value of the gravels.

Pannings taken from the toe of gravel faces and from watercourses cut through the gravels are interesting, but inferences drawn from the gold obtained are usually very misleading. Furthermore, it must not be inferred that a placer claim which returns good wages to a small party of working mates will necessarily pay dividends to a company working on a large scale.

Working on a small scale the miners are always on the track of the gold. If the lead is lost the fact is known at once; but working on a large scale, where the shifting of quantity is an important factor in order to insure adequate returns for the capital invested, rich and poor gravels alike are moved, thereby reducing the general average.

**CALCULATING THE AVERAGE VALUE.**—The average value per cubic yard is found by multiplying the number of grains of gold per cubic yard found in each hole by the depth of the hole in feet, and dividing the sum of these products by the sum of the depths in feet, as follows:

NUMBER.	Depth of Hole in Feet.	Grains of Gold Per Cubic Yard.	Products.
1	14	3	42
2	15	4	60
3	18	2.5	45
4	15	3.5	56
5	13	3	39
6	14	5	70
7	12	2.5	30
8	10	9	90
9	9	6	48
10	14	4	56
Totals	134		536

The sum of the products is 536, and of the depths 134, therefore the average value is  $\frac{536}{134} = 4$  grains of gold per cubic yard. The average depth is  $\frac{134}{10} = 13.4$  feet.

The area of the ground and the mean depth being known, the total cubic content is easily determined; but ample allowances must be made for the possible inequalities of the bottom, etc.

Dredging for gold in river channels, river terraces, lagoons, etc., and the working of placer deposits by hydraulic sluicing and elevating are conducted on a large scale in California and New Zealand.

At the end of 1903 there were in the South Island of New Zealand 272 dredgers, of which over 200 were working, the balance being under repairs, or removed to other ground, standing idle, wrecked, etc.

At the end of the same year there were 2932 water races, having a total length of 6852 miles, and carrying 12,285 cubic feet of water per second; and 2346 tail races in connection with placer mining.

The experience of gold dredging and hydraulicking in New Zealand has proved conclusively that where the ground has been systematically worked by an experienced engineer practically no failures are known.

MINE SAMPLING AND ORE VALUATION.

In the majority of mines sampling proceeds simultaneously with the mine development, the results being recorded on assay plans, which are generally longitudinal or stope plans. Where the sampling during development has been carefully and systematically done, the averages should approximate those obtained by the mine examiner.

**SAMPLING EQUIPMENT.**—This includes new sample bags of canvas or stout calico, say 14 inches long and 9 inches wide; a canvas sheet, about 6 feet long and 5 feet wide; a short-handled 4-pound or 5-pound hammer; a gad or two; small linen tape or foot rule; and a number of small metal tags or strips of soft wood, each with a distinctive number or mark; and a stout canvas lock-up sack for the safe custody of samples.

**PRACTICAL SAMPLING.**—Begin the sampling of a level at the end of the main crosscut, or at some point easily located with respect to a survey peg on the mine plan.

When the whole width of the vein or seam is exposed in the drive it is customary to sample the higher or foot wall portion lying on the back of the level, as the lower portion may be partly under foot and often covered with mud and water.

Divide the level into sections of 5 feet, 10 feet or more, according to the extent of the open ground and character of ore. Mark the divisions with chalk, or by blackening the wall with a candle flame.

With respect to the sampling intervals, it is well to remember that a large number of small samples taken at short intervals are often more reliable than a small number of large samples taken at wide intervals.

When the ore is known to be consistent in value, and is exposed in long stretches, the sampling intervals may be 20 feet apart; but when the vein is somewhat irregular in width and value the 5-foot intervals will give the most confident results.

**RECORD OF SAMPLES.**—Carefully measure and record the width of the vein in feet and inches at each interval.

A simple and accurate method of recording the sampling intervals, widths and sample numbers is to draw a diagram in field book representing a longitudinal section of the level. On this diagram, which

need not be drawn to scale, all the necessary information can be shown graphically. This method has also the further advantage that the assay values can afterwards be filled in at the different intervals, thus completing the record.

The widths, numbers and values are commonly recorded on mine assay plans in different colored inks, according to the individual fancy of the engineer; but this is not necessary in the examiner's field book, which is a private record.

**BREAKING THE SAMPLES.**—Dress the face down with a pick, so as to expose a fresh surface, and, if necessary, clean it with water.

With the hammer and gad break a sample at each interval, allowing the material to fall onto the canvas sheet, or into a stiff felt hat held by an assistant.

The sample is taken from a groove cut at right angles to the plane of the dip; or, in other words, across the thickness from wall to wall, as shown in

the figure, at the sampling intervals marked 1-8. In some cases it is necessary to square the vein on the back of a level or stope in order that the true width from wall to wall may be exposed for sampling.

In ore of fairly uniform hardness the width of the groove will vary from 4 inches to 6 inches, and from  $\frac{1}{4}$  inch to  $1\frac{1}{2}$  inch deep. The sample will generally weigh from two to ten pounds for every foot of vein or bed.

When the vein matter is arranged in distinct bands of crustification—this is with a comb structure—it is advisable to sample each band separately to determine where the values lie.

Wide lodes should also be sampled in widths of 2 or 3 feet, as sometimes the values are carried by the foot wall portion; sometimes by the hanging wall or central portion. In such cases a single sample taken from wall to wall may convey quite an erroneous impression as to the commercial value of the lode.

Where a level is driven on a wide lode, only a small portion of the ore is exposed for examination. In such cases it is customary for the management during the progress of development to crosscut the lode at intervals of 20 or 50 feet, according to the metaliferous character of the ore. These crosscuts will afford the examiner an opportunity of sampling the lode from wall to wall in such manner as the case may require. Where there are no crosscuts through the lode from the level, the full, or, at any rate, the payable, width of ore will generally be found exposed in the stopes.

It often happens, in the case of flat-lying veins, that the level has been driven on the foot wall of the

is rejected, and the assay sample broken down from the fresh surface exposed in the cut.

With uniformly soft material throughout, a pick may be safely used in breaking the samples; but with hard ores, or ores containing hard and soft patches, the hammer and gad must alone be used, as the pick is liable to find the soft places more frequently than the hard, with the result that a relatively larger proportion of the soft ore is broken than of the hard.

If the softer material is richer than the harder, as it often is, manifestly the sample will be unduly enriched; but if poorer, then the sample will be impoverished. In any case the assay value will not represent the true value of the ore.

**SAMPLING ON FLOOR OF LEVELS.**—In cases where the ore has been stoped out above a level it may be necessary to sample the vein along the floor. Here the rails, sleepers, water and sediment will increase the difficulties of the sampler. The blasting will have shattered the ore, and the interstices will have become filled with sediment either richer or poorer than the ore itself. In these circumstances the sampling must be conducted with much care and judgment.

**SAMPLING SPECIMEN VEINS.**—The valuation of gold-bearing veins in which the gold occurs in isolated bunches or patches at irregular intervals, or only at the intersection of cross veins or indicators, is impossible by the ordinary methods of sampling. Even bulk or battery tests are not

to be relied upon, as the values generally lie in a very small space. Thus, while hundreds of ounces of gold may be found in the space of a few yards, the ore for long stretches on both sides may contain no gold whatever. The valuation of such properties is a problem of almost impossible solution.

**SAMPLING OF STOPES.**—Stopes are merely a succession of horizontal drives. They are sampled in the same manner as levels. Samples are broken from the back, sides and working faces, according to circumstances.

When the width of the vein is less than the width of the stope, the vein and the rock must be sampled separately, the widths of each being carefully noted.

**SAMPLING OF WINZES.**—Ore exposed in rise and winzes is valued by breaking samples at 5 or 10-foot intervals from grooves cut at right angles to the plane of the dip. The thickness of the ore is measured and recorded on a diagram in the field book, together with the sample number at each interval.

(TO BE CONTINUED.)

A Characteristic California Mine.

The Gwin mine in Calaveras county, Cal., is a typical California mine in slate rocks. The mine was discovered in the early days of mining in Calaveras county, and under the original ownership it was worked to a depth of over 1200 feet. After an idleness of many years the mine was reopened by the

Gwin Mine, Calaveras County, Cal.

vein, or that the level has been timbered for the stoping. In these cases there is no exposure of the ore in the level, and the samples must be obtained from the stopes overhead.

When sampling a lode composed of very soft, friable or sugary ore it is advisable to expose a fresh surface by cutting a groove 6 or 8 inches wide and several inches deep. The material from this groove

present owners, the Gwin Mine Development Co., who have equipped and are operating the property in an up-to-date manner. The mine is at present over 2000 feet deep, and is the deepest mine in Calaveras county, and is operated through a vertical shaft. The accompanying engraving shows the surface works. The ore is treated by amalgamation and concentration.

# Mining and Metallurgical Patents.

PATENTS ISSUED MAY 23, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AMALGAMATOR.—No. 790,000; J. J. Peacock, Chicago, Ill.

In machine of character set forth, combination with suitable sluice provided with well having imperforate end walls, of cylinder rotatably mounted in bearings inside end walls and dipping into well, cylinder being positively restrained by bearings against rising.

ROLLER FOR DREDGER LADDERS.—No. 790,210; S. L. G. Knox, Milwaukee, Wis.

Built up roller for elevator dredgers and like, comprising shaft, disks mounted on shaft, hard metal shell carried by disks, plugs of softer metal cast in shell, and rivets passing through plugs and securing shell to disks.

CORE DRILL APPARATUS.—No. 790,331; C. A. Terry, New York, N. Y.

In core drilling apparatus, combination with drill rod, plug or coupler secured thereto, and outer core barrel rigidly secured to plug or coupler, of headed stud carried by plug or coupler, an inner sleeve rotatably supported upon headed stud, head or coupler provided with water chamber, and passage leading therefrom to between inner sleeve and outer core barrel.

CHARGING MECHANISM FOR BLAST FURNACES.—No. 790,271; D. Baker, Newton, Mass.

In combination with furnace, track leading to top of same, car traveling on track and adapted to receive materials to be charged into furnace, plurality of charging stations at lower end of track, source of supply for charging stations, and means for conveying materials from source of supply to stations and charging them directly into car.

SMELTING FURNACE.—No. 790,825; C. E. Glafke, Los Angeles, Cal.

In smelting furnace inclined cylindrical smelting chamber having ends partially closed, closure extending from outer wall toward center and extending around entire circumference; baffle in chamber near lower end; means for feeding ore into upper end of chamber; means for feeding products of combustion into upper end of chamber; and means for rotating chamber.

AMALGAMATOR.—No. 790,445; T. J. A. Macdonald, Detroit, Mich.

Amalgamator comprising inclined table over which ore pulp is adapted to flow, well in table containing amalgamating material, cylinders revolving in well and standing obliquely to line of travel of ore pulp and transversely arranged cylinders also revolving in well having channeled peripheries over which ore pulp is adapted to pass.

CONCENTRATOR.—No. 790,342; H. H. Campbell, Steelton, Pa.

In ore separator, combination of table, series of magnets arranged adjacent thereto in row extending from near one corner of table to nearly diagonally opposite corner, means for reciprocating magnets transversely to table, and means for magnetizing and demagnetizing magnets at predetermined times, and means tending to carry material in direction transverse to that of magnet series.

PROCESS OF REDUCING METALLIC COMPOUNDS.—No. 790,389; E. F. Price, Niagara Falls, N. Y.

Process of recovering from ores, metals whose temperatures of reduction and volatilization are approximately same, which consists in heating charge of compound and reducing agent in electric furnace, keeping maximum temperature of charge at point which will substantially prevent volatilization of reduced metal, removing reduced metal from region of maximum temperature as it is reduced, and collecting scattered particles of reduced metal by introducing alloying metal into furnace and causing it to percolate downward through charge.

FRAME FOR MINE TRUCKS OR OTHER SIMILAR VEHICLES.—No. 790,759; G. Stott, Johannesburg, Transvaal.

In truck or like vehicle combination with frame comprising single centrally disposed member, member being adapted to carry standards or supports for pan and being of channel section, beam secured within member, horizontally disposed flanges on member and plates secured to flanges and carrying axle boxes.

ROCK DRILL MOUNT.—No. 790,506; M. Kuzel, Penzberg, Germany.

In drill mount, combination, with standard, bifurcated sleeve rotatable thereon, means for adjusting position of sleeve vertically on standard, worm wheel adjustable on standard by means of spline and groove and occupying position in bifurcated portion of sleeve, worm carried by sleeve and engaging with worm wheel, and crank for operating worm, of arm projecting from sleeve, and drill mounted on arm at point within horizontal plane embracing worm, and worm wheel, and passing through transverse axis of sleeve.

PROCESS OF SMELTING METALLIC COMPOUNDS.—No. 790,391; E. F. Price, Niagara Falls, N. Y.

Process of smelting metallic compound or compounds containing iron and chromium and producing ferro-chromium containing a definite percentage of carbon, which consists in providing electrically conductive charge containing predetermined amount of carbon, establishing electric arc within charge, surrounding zone of reduction and protecting electrodes from oxidizing and cooling effect of atmosphere by considerable body of charge and maintaining between electrodes minimum potential difference requisite to effect reduction, thereby preventing loss of electric current by leakage through charge and heat radiation.

PROCESS OF RECOVERING METALS AND OXIDES FROM SOLUTIONS.—No. 790,429; A. Gutensohn, Southend, England.

Process of recovering metals and oxides from solutions containing same, which consists in mixing solutions with alkaline solution, mixing product with solution containing alkali and resin, withdrawing coagulated mass, separating mixture therefrom and retorting same to distill off resin.

## The Semi-Precious Stones of the United States.

Written for the MINING AND SCIENTIFIC PRESS by  
E. A. REED, A. M.

Between the gems and the semi-precious stones it is difficult to draw the dividing line, as so many of them overlap into the other class. Those which may properly be considered only semi-precious often present such fine specimens that they are mounted and worn with good effect as jewels, while on the other hand the gems are sometimes offered in inferior grades.

Among the true rubies which are found in the Cowee valley, in North Carolina, there are also specimens of pink and red corundum which are enclosed in bright greenstone. The contrast is very pleasing, and the product is sold under the name of ruby matrix. The same combination is found in opal and turquoise; the emerald, also, being cut with its gangue, is offered as a jewel under the name of emerald matrix.

**AGATES.**—The agate is a variety of chalcedonic quartz which is distinguished by its banded or clouded appearance. The bands or layers are either parallel or concentric, and either in straight, circular or zig-zag forms. The natural colors of agates vary greatly, being either gray, red or brown. Some of them are classified under the head of onyx, or if the colors are red and white, they are called sardonyx. Many of them, however, are artificially colored.

An object of great scientific interest is the inscribed Chaldean agate ax now in the Morgan collection of the American Museum in New York. This ax was obtained by Cardinal Borgia while at the head of the propaganda. The Contessa Borgia offered it to the British Museum about twelve years ago for \$15,000 or \$20,000, but her extravagant price prevented its purchase by that institution. It was ultimately bought for about 15,000 lire and brought to America.

Small banded agates of much beauty abound on the shores of Lake Superior, while larger and finer specimens are plentiful in western Texas.

Much of this material is worked up into vases, paper weights, ash trays, etc. It is also mounted for use in jewel boxes, watch charms, scarf pins and other articles both useful and ornamental.

**MOSS AGATE OR MOCHA STONE.**—A chalcedony containing dendritic or moss-like markings. These intrusions of color are usually composed of one of the manganese oxides. In the Chinese moss agates they are often green, having been artificially colored.

Moss agates abound in many places in the United States, especially in Wyoming.

From 1896 to 1902, inclusive, the total value of agates in our country was officially reported at \$13,000.

**AGATIZED WOOD.**—Wood which has been changed to opal is called opalized wood, and some beautiful specimens are found near Clover creek, in Idaho; it is also common in Oregon and California.

Wood which is silicified by silica and still having the structure of the original material is called agatized wood. A marvelous amount of it is found in the petrified forest of Arizona, which is near Holbrook, and has been made more accessible by a railroad station at Adamana. From this point the ground can be reached by a drive of 6 miles, although the most remarkable portions of it are farther away.

At the first deposit there are several sections of land strewn with the fallen and broken trunks which have been washed out of the grayish sandy material in which they have been buried. Here is the noted chalcedony bridge, where one of the finest logs lies across a deep ravine, with the ends resting upon the banks and partially covered. This log is about 4 feet in diameter at its base and it forms a natural bridge nearly 50 feet in length.

The second deposit, lying a few miles to the southeast, covers several hundred acres and presents a difference of material.

In the first deposit much of the wood is broken and scattered over the ground; but here we have many large trunks which are only broken across, making cylindrical sections 5 or 6 feet in length. They are in a better state of preservation than those of the first, probably because they have been more recently washed out and have had shorter exposure to atmospheric action.

Silicified wood is also found in some abundance in the Rocky mountains and a forest in Yellowstone Park resembles that of Arizona.

This beautiful product is utilized by manufacture into vases, heads of canes and umbrella handles, while whole transverse sections are used as table tops.

During the seven years preceding 1903 the output of silicified and opalized wood in the United States was valued at \$31,000.

**TOURMALINE.**—This is one of the most beautiful of the semi-precious stones, many of the finer specimens being mounted and worthily worn as gems. In composition they are very complex borosilicates of aluminum, magnesium, iron or alkalies, falling under four types: The lithia group is often beautifully col-

ored and affords the best gem material; the iron, and the magnesia-iron groups are usually black or brownish black; and the magnesia group is commonly brown.

These general types are again subdivided according to color: The colorless tourmalines are called achroite; the black varieties are aphrizite and schorl; the blues, whether they are very pale or of a deep indigo shade, are classed under the head of indicolite; this also includes the brilliant blue known as Brazilian sapphire; the green tourmalines are called Brazilian emeralds; while the red ones, whether they are of a deep ruby or a pale pink, are known as rubellite. Even these are again subdivided into other classes. Having a hardness of 7 to 7.5 and a specific gravity of 2.94 to 3.3, they take a brilliant polish.

Tourmaline is usually found in granite, gneiss or mica slate. It occurs also in dolomite or granular limestone and in certain contact rocks near dikes of igneous rocks, also in rolled pebbles in alluvial deposits.

The physical properties of tourmaline are very interesting. It becomes highly electric under the influence of either heat or friction, and it has a remarkable polarizing action upon light, therefore plates which are cut from transparent crystals parallel to their length are used in optical experiments when mounted in the tourmaline pincers or tongs.

For 200 years Brazil has been one of the great sources of supply of the finer crystals. Ceylon, India and Burmah also produce some good gem material, the latter locality especially yielding some rubellites which rival the ruby itself in depth and brilliancy of coloring.

Rubellite and green tourmalines occur in Siberia. These stones are also found in great variety in the mining districts of the Ural mountains. One specimen from this locality is of great interest from the fact that, like alexandrite, its pure green color changes to a ruby red in artificial light, and this is only the second mineral showing this remarkable property. (Bull. Ural Soc. Nat. Sci., 1901, Ekaterinbourg, vol. 22, pp. 26-36).

There is a famous locality on the Island of Elba which yields pink, green, white, red, black or parti-colored crystals.

In Canada beautiful greenish-yellow crystals are found in the limestone of Great Calumet island; amber colored ones at Fitzroy, Ontario; transparent brown at Hunterstown, Quebec, and black in other localities.

In the United States one of the most famous localities is at Haddam Neck in Connecticut where green and parti-colored crystals are found which make beautiful gems. Mr. Ernest Sehernikow of New York, who was engaged in exploiting the albite quarry where they occur, made a representative collection of about eighty specimens and presented it to the Oxford Museum. This was very carefully investigated by Mr. H. L. Bowman who described it fully in the Mineralogical Magazine of London. His paper treats of ten species of which the collection contains examples, and mentions three others which are not there represented.

Maine is another State famous for fine colored tourmalines, many of which have been found at Auburn, Hebron, Standish, Andover, Norway and Paris. A great discovery of these stones was made at Mount Mica, near Paris, in 1820, and it is still yielding fine specimens of red, green and parti-colored tourmalines. Some of these crystals are over an inch in diameter and they may be red at one end and green at the other or they may be of a transparent ruby red inside and nearly or quite surrounded with a brilliant green. One blue crystal was found here which measured 9 inches in length.

Red and green tourmalines are found at Chesterfield, Massachusetts; the crystals are, however, small, curved, nearly opaque and often quite fragile; green crystals with distinct prisms of red on the inside are found in this locality. At Goshen, Massachusetts, similar varieties occur and the blue is met with in great perfection.

Fine black crystals occur at Pierrepont, N. Y., while good brown ones are found at Gouverneur in the same State, and also at Hamburg, N. J.

Southern California, however, now promises to be one of the best localities on account of recent discoveries there. Some of the stones from this region are half red and half green with a perfectly sharp demarcation between the two brilliant tints.

Several mines have recently been opened in Riverside and San Diego counties, and in the latter locality colored tourmalines have been found which are of remarkable size and beauty, although some of them have been broken in taking them out. Crystals are here found which are a foot long and 3 inches in diameter with a red central core (rubellite) and a blue exterior (indicolite), separated by a pale intervening zone.

So far as the official figures go, during the seven years preceding 1903 the output of tourmalines in the United States was valued at \$65,625.

**AMAZONSTONE.**—A beautiful green feldspar, a variety of microcline. Its color range includes several shades of green varying from the palest hue to a strong deep tint. So far the finest specimens have come from Pike's Peak, but inferior crystals are found in several localities. There is a cleavable

amazonstone which is found in goodly quantities at Amelia, Virginia, and being worked with comparative ease it may be used for a variety of decorative purposes. In the United States the value of the output varies from \$200 to \$1000 per year.

**CATLINITE OR PIPESTONE.**—This is a compact clay slate varying in color from ashen gray to deep red. It occurs principally in Pipestone county and other localities in Minnesota. But it is also found at Plandean and Sioux Falls, South Dakota; in Sac county, Iowa; Barron county, Wisconsin, and elsewhere, in the region of the upper Mississippi and Missouri river country. It appears to have been early utilized by the Sioux Indians who manufacture it into pipes. It is also used for paper weights, ash trays, etc. Although of comparatively small importance, it has nevertheless found a place in commerce, and during the seven years preceding 1903, the output was valued at \$15,000.

**BLOODSTONE OR HELIOTROPE.**—One of the varieties of quartz, which is really a translucent to opaque Jasper of a deep green color, interspersed with red spots. A discovery has been made of true bloodstone in Wasco county, Oregon, by Miss Nettie Hayes. Good specimens were here found which were of a deep rich green, with the red spots which characterize the true stone. Some of the pieces are as fine as those from India, but it may be some time before the locality is exploited sufficiently to make the output an article of commerce.

**CHRYSOPIRASE.**—A green, or bluish, or yellowish translucent chalcedony. An occurrence of chrysoprase is reported about 16 miles from Asheville, near Morgan Hill, North Carolina. The material is encountered in several parallel seams and within a few feet of each other. At the surface the color is pale green, but as the rock was opened down to about 4 feet the color became darker and richer. Beyond a little test work no development has been attempted and the value of the deposit cannot as yet be properly estimated.

It is found, however, in other localities, and during the seven years preceding 1903 the product of chrysoprase in the United States was valued at \$7400.

**CHLORASTROLITE.**—From chloros (green), aster (a star) and lithos (a stone)—literally a green star stone. It is a variety of prehnite, bluish-green in color, sometimes mottled and somewhat chatoyant on the rounded sides. It takes a high polish, and thus becomes very ornamental. It is found in the form of rounded pebbles on the shores of Isle Royale, Lake Superior, where it is obtained from the trap.

During the five years preceding 1903 the product from this point has been valued at \$18,000.

**SPODUMENE.**—A mineral occurring in monoclinic crystals of a prismatic habit and in cleavable masses. It is much like feldspar in appearance, but it has a higher specific gravity (3.13) and a more pearly luster. Its hardness is from 6.5 to 7.

Transparent spodumene affords gems varying in color from green of various shades to yellow or yellowish white; also, colorless or faint red to amethystine specimens may be found.

It occurs in Sweden, in the Tyrol and in Scotland. Most of the gem spodumene, however, comes from Brazil where it occurs in crystals closely resembling in color the chrysoberyl, which has not as yet been found to any commercial value in the United States.

Specimens of spodumene have been found at Windham, Me.; Winchester, N. H.; Goshen, Chesterfield and Norwich, Mass., and Brookfield, Conn.

Recently a very remarkable discovery of unaltered lilac-colored spodumene (kunzite) has been made in California. A mile and a half northeast of Pala, in San Diego county, at the notable deposit of colored tourmaline above noted, these crystals of spodumene were obtained at a depth of 50 feet. This locality is therefore unequaled in the world as a deposit of lithia minerals.

The spodumene crystals are beautiful in their color tones, varying from a deep pink-purple lilac in those taken from a great depth to a pale, almost colorless, tint which is apparently due to the action of sunlight. They are of extraordinary size, transparency and beauty and are unrivaled by those from any other known localities. Six of the California spodumene crystals vary in weight from 7.70 ounces troy to 17.1 ounces.

**HIDDENITE OR LITHIA EMERALD.**—A variety of spodumene varying in color from a yellowish to a deep emerald green tinged with yellow, the crystals often being yellow at one end and green at the other. The deeper colored kinds afford a gem resembling emerald but having a greater variety of color. Hiddenite is at present known from but one locality—Stony Point, in North Carolina—and nowhere in the United States has either variety as yet been found in any sufficient quantities to appear in the figures of the official reports.

**QUARTZ.**—Quartz crystallizes in the hexagonal system, the most common form being a six-sided prism. When pure it is colorless, and fine specimens are sometimes represented to be white topaz. They are also cut, mounted and sold under the name of Lake George diamonds, and other names. Other varieties are red, or brown, or yellow, green, or even blue or black.

On account of the great differences of color and

texture and its use as a semi-precious stone, many names are given to the various members of this large family, although they are chemically one substance. Of these, several have already been noted: Agate, agatized wood, amethyst, bloodstone, chrysoprase, etc. Besides these we may mention:

**CARNELIAN.**—A reddish variety of chalcedony passing into red, yellow and brown. It is translucent, takes a fine polish and is often of a clean bright tint. The natural colors are intensified by exposure to the sun's rays or to artificial heat.

**CAT'S EYE.**—Is a translucent quartz exhibiting opalescence or chatoyancy when cut cabochon. The term "cat's eye" is applied to a number of minerals which when cut in this way exhibit a peculiar opalescence characterized by a line, or ray of light across the stone resembling the contracted pupil of the eye of a cat. Such gems may be opaque, translucent or transparent, and may be of any color or colors.

**FLINT.**—A more or less impure chalcedonic quartz, usually gray, smoky brown and brownish black.

**HYALITE.**—Is clear glassy silica occurring in some lavas.

**JASPER.**—A massive quartz or chalcedonic rock, presenting little beauty until polished. Colors, dull red, green, brown, yellow and sometimes blue or black. When the colors appear in bands it is called ribband jasper; if zoned with colors it comes under the head of Egyptian jasper. This material takes a high polish and is extensively used for vases and other useful or ornamental articles.

**PRASE.**—Is a green, somewhat spotted, massive quartz.

**ROSE QUARTZ.**—Is usually massive. It is generally of a rose color, but may be of a pale pink. It is vitreous and sometimes opalescent. It is, however, liable to lose color by continued exposure to a strong light.

**VENUS HAIR.**—Is quartz penetrated with needle-like crystals of rutile and presenting the appearance of being covered with short threads or scattered hairs.

**SMOKY QUARTZ.**—Is of a smoky gray or yellowish color. The crystals are often pellucid, but occasionally the color is so deep as to render them nearly opaque with a brown appearance.

Since 1897 many pockets of smoky quartz, or cairngorm, have been found on the Littlefield farm, Auburn, Me. Several tons of crystals have been obtained, and one perfect specimen weighing twelve pounds was found near the farm of A. S. Berry in a deposit of large quartz crystals, feldspar and gem tourmalines. A perfect 3-inch ball was cut from a smoky quartz crystal found here.

**ROCK CRYSTAL.**—Transparent and colorless, this includes the pure crystals of quartz. Recently developed uses of this material are found in the manufacture of fibers for suspending small magnets and mirrors used as galvanometers, and in the manufacture of spectrum tubes, the quartz being fused by the oxyhydrogen blowpipe. Quartz fibers are used for galvanometers because they show no torsion, and the minors have no permanent deviation from the true position when at rest. Vessels made of fused quartz may be heated to a white heat and then plunged into cold water without injury, hence the value of these tubes in the study of gases at high temperature. Large quantities of rock crystal have been obtained in Calaveras county, Cal., near Mokelumne Hill, in a gravel mine.

**MILKY QUARTZ.**—A massive vitreous variety, having a milk-white color. It is sometimes opalescent and is used for many purposes. When finely crushed it is used by porcelain manufacturers for making glazes. Quartz sand and pure quartz finely ground are used for making glass. It is also used as an abrasive, either as sand paper or in fine powder. In these forms it is used for dressing stone and leather.

During the seven years preceding 1903 the three varieties of quartz crystal, smoky and rose, were produced in the United States to the value of \$89,950.

### A New Four-Valve Engine.

A new type of four-valve engine has been recently placed on the market by the Atlas Engine Works of Indianapolis, Indiana, in which especial attention has been given to the matter of steam economy, and a number of radical changes made with this in view.

Chief among these is the placing of the steam and exhaust valves directly in the cylinder heads, rather than at the top and bottom of the cylinder, which is designed to result in a reduction in the clearance, and to make the saving of steam effected in this way quite material.

The steam valves are operated directly from a movable eccentric forming a part of the automatic

shaft governor, and are thus independent of the exhaust valves. The latter are operated from a fixed eccentric on the main shaft, to insure uniformity of compression under all conditions of load and pressure. The connections are all made of the "straight line" type, and involve no multiplicity of parts. Both the steam and exhaust valves are double ported, and it is claimed that practically no wire drawing of steam whatever exists in this type of engine. Various tests made in the Atlas shops, as well as in the field, indicate a steam consumption virtually that of the Corliss type.

In addition to the line of medium speed engines, the builders are also offering a high speed, center crank engine for electrical service. This type has the reciprocating parts enclosed under an oiltight hood. At each revolution of the shaft the crank, crank pin, crosshead pin, crosshead guides and main bearings are showered with oil from a reservoir in the crank pit, into which the connecting rod dips. Oil from the same source is also delivered by centrifugal force to all other reciprocating parts, and is finally returned to the reservoir in the crank pit. This has proven to be an effective system of lubrication.

### The Cyanide Process.

NUMBER II.—CONCLUDED.

Written by R. STUART BROWNE.

The construction of zinc boxes is such that they may be used for either up or down flow by simply reversing the box end for end.

Punched sheet iron makes a better screen for the boxes than wire. The wire rusts more quickly and breaks down under the weight it has to support. The screen should always be a flat sheet without any vertical sides. A tray prevents the close packing of the zinc, for it leaves a space of about half an inch around the sides where the solution can come up and form channels.

Within recent years there has been a tendency to change from the old style of box and use what is known as the individual or single compartment type. These are boxes with a single compartment arranged for up flow, and are used in series, the number depending on the size. Some are connected together by suitable pipe fittings, while others are arranged to overflow into the lower box. Small tanks from 2 to 5 feet in diameter, and from 3 to 5 feet high, have been used for this purpose with a great deal of success. The cylindrical form is easier to pack and the tendency for the solution to channel is much reduced. They are more convenient to handle, less liable to leak, more portable, and much cheaper than the rectangular, multiple compartment box. It is quite likely that this form will entirely supersede the old boxes in the course of time. The number of boxes in a plant depends on the amount of solution handled and the way the gold precipitates. Separate boxes are used for handling the weak and strong solutions. The boxes should always be covered and a strong lock put on. Launderers are sometimes attached to the sides to facilitate the cleaning up. They are handy and reduce the mechanical losses in handling the slimes.

Below the precipitating boxes are the sumps. Two are generally used, one for weak and one for strong solution. In a very large plant there may be more. They are always placed at the lowest part of the mill. Sometimes where it is difficult to get sufficient grade the sumps are set into excavations made in the ground and the earth filled in around them. This should never be done. If it is necessary to set them underground, a space should be left around them so that they can be examined.

The solution tanks are always placed above the level of the top of the leaching tanks and are generally the highest tanks in the mill. Two tanks are used, weak and strong.

In a typical crushing mill there would be no solution tanks, but two extra sumps would be installed instead. A water tank should be provided. This should be elevated above the leaching tanks. Sometimes a small tank is used for dissolving the solid cyanide, but it is not necessary. The best way is to put the cyanide into a perforated box suspended under the pipe that delivers the solution. When the solution is pumped in the cyanide rapidly dissolves.

One of the most important features about a cyanide plant is the pipe system. This must be designed strictly in accordance with the treatment the ore is to be subjected to. The essential feature of a good system is simplicity. A complicated system, while it may possess certain good points, is apt to confuse the solution man and cause him to run to waste valuable solution.

All metal about the plant should be iron, as it will resist the corroding action of the solutions better than any other metal. Brass or copper should never be used, if it can be helped. The best valve for all-round use is the cheap cast iron plug valve. These valves are not as easy to manipulate as the more expensive gate valves, but they do the work and seem to have the preference.

The equipment and design of the clean-up room

needs careful attention. The mechanical losses from the handling of the gold slimes amount to a great deal, and though it is not possible to eliminate them altogether, they may be reduced to a nominal amount by taking the proper precautions. The clean-up room should adjoin the precipitating department, to avoid transporting the slimes any great distance. Both should have a concrete floor sloping to a drain pipe that discharges into a sump. In the United States the precipitate is usually refined by the acid process. The acid refining is conducted in a tank provided with a sheet-iron hood to carry off the gases. In large plants mechanical stirrers are used in the tank, but in small mills a wooden paddle will suffice. Lead tanks are the best for conducting the acid treatment in, but as they are very expensive and difficult to transport, redwood tanks are generally used in preference. They may be used without a protective coating, but it is best to paint them with P. & B. paint, after which acid will have no effect on them.

Below the acid tank there should be a settling tank large enough to contain all of the waste solutions from the refining operations. After a few days the top solution is decanted off and run through a filter to insure against any loss. To remove any excess of moisture from the gold slimes, either a filter press or vacuum filter pan is necessary. The former is to be preferred. Considerable hot water is necessary in the room for washing out the acid and salts from the precipitate. A convenient way of obtaining it is to have a cold-water tank with a steam pipe leading into it. By turning on the steam hot water can be obtained in a few minutes. A good way to dry the precipitate is by means of a steam coil arranged inside of a sheet-iron box with shelves to support the pans.

In designing the mill an important point to consider is the economical filling of the tanks with ore. If reservoir tailings are being treated the plant should be located below the supply. Then they can be shoveled into cars and dumped into the tanks from an overhead track. If the plant must be located above the reservoir, run the cars up the incline by means of a hoisting rope, and then run them to the tanks by hand. If the tailings have to be transported in wagons a bridge with a grating floor should be built over the tanks, so that the wagons can drive on to it and dump their loads directly into the leaching tanks. If the tailings are near at hand scrapers can be used instead of the wagons and the cost of shoveling done away with. Small plants can make use of scrapers to convey the tailings to the side of the tanks and then they can be shoveled in by hand.

In dry crushing mills the ore is always elevated into bins and drawn off into the tanks as desired. Some mills use shaking spouts to convey the ore from the bins, but the better way is to use ore cars running on a track built over the tanks. In handling dry crushed ore there is always a large amount of dust created, which represents a loss if it is allowed to get away. To prevent this, arrangements should be made for sprinkling the pulp at the earliest possible stage with either water or dilute cyanide solution. It should not contain any more moisture than is necessary to allay the dust. In wet crushing mills the handling of the pulp is complicated because of the necessity of removing the slimes previous to cyaniding.

**SLIME TREATMENT.**—The treatment of slime has always been the most serious problem connected with the cyanide process. It has been solved in a great many instances, but such successes have not resulted in the working out of a universal method of treatment, for the reason that slimes vary in their physical properties.

Slime treatment may be divided into three distinct operations, but it will be necessary to consider only the first two.

1. Dissolving the gold.
2. Separation of the solution from the slime.
3. Precipitation of the gold.

**DISSOLVING THE GOLD.**—This is always accomplished by agitating the slime in a cyanide solution. The question of the best form of agitation is an open one. Mechanical agitators of the paddle type are very good, but as they require considerable power to operate them, they are not much used. Centrifugal pumps are used a good deal and are satisfactory in every respect except that the cost of repairs is considerable. They are usually used in connection with conical bottom tanks arranged so that the slime can be drawn off from the bottom and thrown back on top. The use of compressed air for agitation is becoming quite common and gives excellent results. The time required to agitate an ore is variable and must be determined by experiment. If the time is short the agitation is continuous, but if long it is intermittent.

**SEPARATION OF THE SOLUTION FROM THE SLIME.**—This is the great problem of slime treatment. There are two standard methods in general use, known respectively as the decantation and the filter press methods. There are also certain patented processes which have much to recommend them, nevertheless have not been very widely adopted, probably because of the royalty question.

In the decantation method, after the gold has been dissolved the slime is allowed to settle for a certain

length of time and the clear solution on top is drawn off by means of a decantation pipe, siphon or pipes arranged around the sides of the tank at different heights. The sludge remaining behind usually contains from 50% to 80% of moisture. To recover the values retained in it, wash water or a weak cyanide solution containing low gold value is added and the sludge agitated to insure a thorough mixture, after which it is again allowed to settle and the clear solution again removed.

In general, two or three decantations will reduce the value of the sludge to a point where it does not pay to bother with it any further. The clear solution withdrawn is sent through the zinc boxes and the gold and silver recovered in the usual manner. The greatest objections to the decantation process are: First, it requires a very large amount of tank room, and, second, it causes the accumulation of large quantities of solution so low in gold value and so weak in cyanide that it becomes a serious problem to precipitate the gold from it.

Some varieties of slime will settle very quickly, while others require so much time that decantation is impracticable. Slacked lime has the peculiar property of coagulating slime and causing it to settle very rapidly. For this reason it is extensively used in slime treatment. The amount used varies from one to ten pounds per ton of dry slime. The proper quantity to add can be determined only by actual experiment.

Another method of separating slime and solution is that which is known as filter pressing. This was developed on the gold fields of Western Australia, where a process was required that needed a minimum amount of water. After the gold is dissolved the sludge is forced into a filter press under a heavy pressure. Clear solution flows out through the filter cloths and is conveyed to the precipitation department, while the sludge after washing is discharged and the press made ready for a new charge.

The filter press consists of a series of hollow frames from 1 to 3 inches thick, according to the nature of the slime, and from 2 to 4 feet square. Between each frame is a filtering surface covered with a cloth. When the press is together it consists of a series of from thirty to fifty independent chambers, each with a separate filtering surface. Arrangements are made for delivering the pulp to the center of each chamber and for washing the cakes after they have been formed. The greatest objections to filter pressing are, first, the high cost of the press, and, second, the cost of operation. Every time the press is filled it is necessary to open it for the purpose of discharging it. Nevertheless, filter pressing is the nearest and best way of treating slimes, provided, of course, that the slimes can be pressed. Some slime is of such a nature that it will pack in the press so that only very thin cakes can be made and the cost of treatment becomes too great.

Special presses have been designed for slime treatment. The largest ones have a capacity of several tons of dry slime per single charge. The time required to put a charge through a press varies from two to three hours, depending upon the porosity of the cakes. The greatest difficulty in filter pressing is to get a cake of uniform density. In charging a press the heavier particles tend to settle in the lower part of the chamber, and this makes that part of the cake the most porous. In washing a cake the wash water will follow along the lines of least resistance, and if the cake is not uniform the washing will be imperfect. For this reason it is necessary to adopt a very perfect system of classification where filter pressing is to be used.

The most rebellious slime is that which consists of the hydrated oxides. This material frequently baffles all attempts to treat it by the methods just described. It may be made amenable, however, by drying it at such a temperature that the water is completely expelled from it. When this is done it becomes very docile and may be worked by any method. For drying this class of ore the best form of furnace is the revolving cylinder of the White-Howell type.

In treating tailings that have accumulated in reservoirs it usually happens that considerable quantities of slime are found that have settled out from the sands. A good way of treating such slime is to plow and harrow it up and then mix it in with the sands in such quantities that it does not interfere too seriously with the percolation.

The fact that fine grinding gives an increased extraction has led to numerous investigations being made along this line, with the result that quite a number of mills have adopted fine grinding. In fine grinding mills the slime problem is not so serious as it would seem, provided that the ore is siliceous. The admixture of a large quantity of siliceous material with slime renders filter pressing a comparatively easy matter. The usual sequence of operations are fine grinding, agitation with a cyanide solution, filter pressing, precipitation of the gold, washing of the cakes and finally the discharging of the press. The success which has attended fine grinding indicates that before long its adoption will be widespread.

**THE CYANIDING OF COPPER-GOLD ORES.**—It is a well-known fact that cyanide has a great affinity for certain copper compounds, and the occurrence of an appreciable amount of them in an ore may make it

impracticable to treat the ore by the cyanide process. Sulphides which have not undergone oxidation are not appreciably attacked by cyanide, but the oxides and carbonates are very soluble.

There are two reasons why the presence of copper is objectionable—first, it causes a large loss of cyanide, which adds to the expense of treatment; second, it gives a great deal of trouble in precipitation. Gold and silver ores containing small quantities of copper are now being treated successfully by the cyanide process, and making a commercial success, but it requires very careful work, and much of it is of a delicate nature, requiring the services of expert chemists. Any lixiviation process which will treat coppery gold-silver ores and give a good extraction will solve one of the most troublesome metallurgical problems of the day.

It is known that ammonia will rapidly dissolve the oxides and carbonates of copper, and, second, that if an alkaline cyanide be added to the ammonia solution containing copper, a solution containing the double salt, cupro-ammonium cyanide will be formed, which will dissolve gold and silver. These reactions form the basis of several processes which aim to treat copper-gold-silver ores.

There is no question but that a high extraction can be obtained by the use of the proper reagents. The weak point is in the precipitation of the metals. D. Mosher, who has some patents covering the process, employs a boiling out method for recovering the ammonia and copper and then precipitates the precious metals from the cyanide solution on zinc shavings. He first leaches the ore with a weak ammonia solution to remove the greater portion of the copper. He then follows with ammonia-cyanide to dissolve the gold, silver and residuary copper, as in the ordinary cyanide process. The fact that the cyanide is destroyed by the copper does not decrease the extraction of the precious metals, for the cupro-ammonium cyanide that is formed has an equal if not greater affinity for them, probably due to its powerful oxidizing action.

The solutions coming from the leaching tanks pass through a continuous still built on the heat exchange principle. Here the ammonia is driven off and condensed in a receiver for further use. The copper is precipitated in the still as the black oxide. The outgoing solution contains the cyanide, together with the gold and silver. This is precipitated in the usual way and is made ready for the leaching tanks again by the addition of ammonia.

The important point in the process is, of course, the boiling out, and the question of expense deserves careful consideration. The patentee claims, and offers figures to prove it, that a still designed to handle 100 tons of solution per day can boil out the same at a cost varying from 15 to 30 cents per ton, depending on the nature and cost of the fuel employed. If this be true, and it seems quite possible, a new and important field is opened up for the cyanide process.

### The Influence of Fine Grinding.

In the discussion following a paper by A. W. Warwick in the Western Chemist and Metallurgist, P. Argall says:

The flint mill and the filter press have made fine grinding, as we now understand it, possible. Before the advent of the filter press in the metallurgy of gold ores, slimes were a bugbear and something to be avoided and yet if we had been called upon to produce 200 tons of slime per day, meaning by slime material that would pass 200-mesh screen or one four-hundredth of an inch-screen aperture, no two of us would have used the same methods to obtain these results; now, however, no one questions the superiority of the tube mill for fine grinding, and with this mill and the filter press it often becomes necessary and even desirable to grind ores to a very fine state of division in order to obtain high extractions or reduce the time of contact between the ores and the solvent. In South Africa the decantation process has been in use for many years in the treatment of the slimes separated from the stamped ores of the Rand, and lately this process has been brought up to a very high state of efficiency, but from the reports at hand it would seem that from the very best plants fully 10% of the gold is lost in a soluble condition; that is to say, it cannot be economically separated from the slime and is discharged with that material from the plants. It does seem rather hard, after getting the gold into solution, to lose so much of it; however, it simply points to the limitations of the decantation process, as there also limitations to the filterpressing of slime, and indeed each and every process has its shortcomings and limitations.

About a year since I was, while in Mexico, called to a tailing plant where both the filter press and the decantation process had failed in the treatment of very slimy tailings produced by arrastras, over a century ago, washed down the side of the hill and mixed with a rich reddish soil, leaves, etc.; a good crop of winter wheat was flourishing in the little valley which held this tailings mixture and it was impossible to distinguish between the soil and the tailings except by assay. A leaching plant had been erected but the material would not leach, then a Johnson filter press making 3-inch cakes 48 inches

square was put in, fully tested and condemned, and lastly a decantation process was installed with like result. I had never seen anything in the way of ore that could not be filter pressed and consequently I took that process first, using one part slime and one of solution; with material of this consistency a cake would ordinarily be made in ten to twenty minutes, but on opening the press after three hours' pumping I found there was but 1 inch deposited on the cloths, leaving a 1-inch space in the center. A second experiment, commencing with twenty pounds' pressure and gradually increasing to 120, did not make a solid cake in five hours, the experiment terminating with the bursting of the press and deluging myself and assistant with liquid mud. The filtration rate was only 300 c.c. per minute from 32 square feet of surface, so I decided the filter press was a first-class failure, so far as the treatment of those tailings was concerned. On investigating the decantation process I found the settling rate varied from 3 inches to 6 inches per day and that it was necessary to wait from ten to twenty days after agitating a tank before decantation could be proceeded with, and so this process, as ordinarily employed, was also a commercial impossibility.

Experimenting in the laboratory, I found that after roasting the slime and mixing it with cyanide solution it settled readily; in fact, after shaking, the solution became clear again in three minutes. Further experimenting showed that the addition of one pound of sulphuric acid per ton of tailings destroyed to some extent the colloidal substances present or at least wrought such a change in the slime as to cause a settling of 5 feet in twelve hours instead of 5 inches in twenty-four hours, which was about the best that could be done without the aid of the acid. I warned the chemist in charge to go as light on the acid as possible and six months after I visited the plant I wrote him for results. He reported he had several times cut down the acid slightly but that immediately the extraction of gold fell off. Here, then, we have a case where the addition of a cyanide not only helps the extraction of gold but also renders the decantation process possible, and, further, neither the filter presses nor ordinary decantation nor leaching could be successfully applied to this peculiar slime.

The difficulty in this case was not alone due to the very fine state of division of the ore, but to what I have described as gelatinous material and organic matter, but more correctly described by Mr. Warwick as colloid hydrates, a definition of slime I am prepared to accept as an accurate and precise definition of that substance that renders finely ground ore unleachable. I have experimented very largely on Cripple Creek ores and some years since had slimy ores crushed to pass a 200-mesh—one four-hundredth inch aperture—then floated off the material that failed to settle in the solution in five minutes, repeating the washing and floating, I believe, half a dozen times. I had left a gritty material that gave a leaching rate of 4 inches per hour, notwithstanding its extremely fine state of comminution. Bearing on this same point, the United States Department of Agriculture shows that wet grinding of rock increases the binding power or tendency of the particles to cement together. "This effect seems to be accompanied by direct decomposition of certain constituents of the rock magma, which results in forming colloidal films on the particles. The word 'pectoid' is suggested to describe this condition. Most rock powders that have been ground wet show an alkaline reaction to indicators, but if the water is filtered out the reaction is not easily shown. This observation is in line with the well-established fact that coagulated inorganic colloids have the power of occluding the bases from solutions of neutral salts."

The remark by Mr. Warwick regarding losing gold in slime by fine grinding, if I understand him correctly, requires modification, for as a usual thing the finer the ore is ground the higher will be the saving by amalgamation, other things being equal. Our South African friends are introducing tube mills to grind the ore finer so that the saving by amalgamation may be increased and the amount of the gold recovered by solution in cyanide decreased, though the combined extraction will of course be much higher.

We have seen that fine crushing for cyanide treatment has been rendered commercially possible by two inventions, both perfected in Westralia. I refer to the tube mill and the filter press. Should fine crushing become universal, as, indeed, it promises to, one naturally asks what is to become of the time-honored stamp mill? The stamp is not a fine crusher in the sense in which the term is used to-day, never was, and never will be. It attempts too much. Each machine has its economic limit, and the day of the one machine is passed and the tube mill has forever established the correctness of successive comminution, that I with others have so long advocated. I have shown that the efficiency of a rock breaker falls off rapidly, when a reduction exceeding four to one is attempted (say 8-inch to 2-inch cubes) and that for reduction below 2 inches rolls are far superior to rock breakers and that for rolls the same proportion of reduction holds good; and, furthermore, rolls reach their limit as fine crushers at  $\frac{1}{16}$ -inch screen aperture in dry crushing and for finer product their efficiency falls rapidly. What, then, is the efficient limit of the

stamp? No one knows. Some hold that a 1250-pound stamp will give as high a tonnage when fed with 2-inch rock cubes as if fed with  $\frac{3}{4}$ -inch cubes. I do not admit this in its entirety, but there is much truth in it, for the reason that in my opinion modern stamp practice has been for many years proceeding on a wrong basis—constantly increasing the weight of the stamp so that it can smash any size rock that can be passed into the mortar, and paying little if any attention to the preparation of the ore with rock breakers and rolls prior to sending it to the stamps. It is just possible that a 1250-pound stamp might sink through a  $\frac{3}{4}$ -inch ore bed and strike the die and so a well-prepared ore would under these conditions show even a lower stamp efficiency than if the stamp were fed with a maximum cube of 2 inches, as in the latter case there would be material on the die that would resist the weight of the falling stamp to the end that the greater part of the energy would be expended in the useful work of crushing the ore. Supposing, however, that  $\frac{3}{4}$ -inch cubes are fed to an 800-pound stamp and the output from the latter stamp was fully as great as the heavier one, as in most cases I know it would be, then the stamp advocates would be prepared to admit there was something wrong, and it only becomes necessary to reason out whether stamps or rolls are the most efficient machine for reducing ores from 2-inch to  $\frac{3}{4}$ -inch cubes, and to this there can be only one answer, as all must admit that the stamp is not a coarse crusher—we have previously seen that it is not a fine crusher, hence if it has an economic range comparable with modern machines it must be somewhere between the extremes given. A recent Rand experiment has shown that a 1250-pound stamp gave at 0.02-inch screen aperture a capacity of five tons per day; at 0.04-inch, 6.5 tons; at 0.05-inch, seven tons, and at 0.08-inch, ten tons per day, and the best all-round results were supposed to be made when crushing through an 0.08-inch aperture. Now if we assume the maximum size feed was 2-inch cubes, the range in reduction to  $\frac{3}{4}$ -inch is 100 to 1. Can any machine have an economic range over such wide limits? The efficiency of the stamp at  $\frac{3}{4}$ -inch is but one 140 pounds per horse power hour; rolls would give 300 pounds per horse power hour, while the roll output per horse power hour at 0.08-inch would also be vastly in excess of the stamp.

The stamp, then, if it survives in modern ore reduction plants, will only be one unit of a series of machines, its range of reduction being restricted to a very narrow limit. My idea of a modern fine crushing plant is, however, as follows: Rock breakers to 2-inch cubes; rolls in series, 2-inch to  $\frac{3}{4}$ -inch; grinding pans,  $\frac{3}{4}$ -inch to  $\frac{1}{4}$ -inch; tube mills to infinity, if required.

M. D. Stackpole in taking part in the discussion said, concerning the settling of slimes, that tables have been prepared giving the comparative value of different chemicals for settling slimes. My experience has been that the value of a settling agent depends upon the slimes under treatment. A recent slime, upon which I have been experimenting, settled with lime slowly and quite rapidly with sulphuric acid or salt. At the present time I am working on an almost pure kaolin, which to the eye appears impossible to handle commercially. When containing 30% moisture it cuts like cheese, and yet it is readily broken up in water and settles very rapidly without the employment of any settling agent. On another slime the employment of every conceivable means failed to induce settling, and the mixture of slime and liquor stood for days without settling at all.

While in Mexico last summer, working upon the substitution of cyanide for pan amalgamation then used, because of insufficient tankage considerable slimes were lost. Stored in the mill were large amounts of concentrates, too low in value to pay for shipment by mules 90 miles to the railroad. An effort was made to treat these concentrates by giving them a chloridizing roast and running them through the mill. A small amount of these roasted concentrates were fed each day with ore into the batteries, and, as long as this custom was followed, practically all of the slimes settled with the sands in the first two compartments of the settling tanks, and the water then ran away from the mill perfectly clear. In this same connection many of us have had to deal with thick layers of foam forming on the top of agitation tanks. This often forms from 1 to 2 feet in thickness, and of such consistency that you can cut a trench to the bottom of it and the sides will stand. Another engineer tells of having this foam 4 feet thick and such consistency that if a plank were laid across it, it would sustain its weight. This foam is caused by the addition of lime to a slime and increases with the lime added. A clear solution, no matter what the amount of lime, will not foam, but if a very small amount of slime be present with the lime, this foam will form.

As this foam is a very objectionable feature, a study of its nature and the causes that lead to it will be of interest.

Some eight years ago I was employed at a plant in which one of the first tube mills of modern type used for mining purposes was in operation. This mill was 20 feet long by 5 feet in diameter, and lined with chrome steel plates. We first filled this with cast iron balls of three sizes, but, because of the rapid wear and the large power required to drive this mill

a little less than one-half full of balls, some substitutes for these balls had to be obtained. The ore from one of the mines was a very hard, flinty, white quartz. We selected pieces of this from 4 to 8 inches in diameter, and filled the mill with them. For the first two days, until the pebbles were rounded, the results were about equal to those obtained from the iron balls, but, after that, they gave excellent results, and with the addition of 400 pounds of this material daily we were able to crush twenty tons of ore in ten hours, 90% of which would pass 100 mesh. I believe we could have obtained a much heavier capacity from this mill had we realized the necessity of a heavy feed, instead of allowing it to take the product from the rolls at the same rate at which it passed through them.

### How to Remember the Wire Table.\*

Written by C. F. SCOTT.

The wire table for the B. & S. gauge copper wire has a few simple relations, such that if a few constants are carried in the memory the whole table can be constructed mentally with approximate accuracy.

**RESISTANCE.**—A wire which is three sizes larger than another wire has twice the weight and half the resistance.

No. 10 wire has a resistance of 1 ohm per thousand feet; No. 7 wire, which is three sizes larger, has .5 of an ohm per thousand feet; No. 4 wire, which is three sizes larger than No. 7, has .25 of an ohm; No. 13 wire, which is three sizes smaller than No. 10, has 2 ohms; No. 16 wire, which is three sizes smaller than No. 13, has 4 ohms. It is easy, therefore, knowing the resistance of No. 10, to find the resistance of Nos. 7, 4, 1 and 000; also, of Nos. 13, 16, 19, etc.

A wire which is ten sizes larger than another wire has ten times the weight and one-tenth the resistance.

As the resistance of No. 10 is 1 ohm per thousand feet, the resistance of No. 0 is .1 of an ohm, and the resistance of No. 20 wire is 10 ohms. As the resistance of No. 4 is .25 of an ohm, the resistance of No. 14 is 2.5 ohms and of No. 24 25 ohms.

In the following table the first column contains the sizes of wire which differ from one another by three sizes. The resistance of each wire in this column is seen to be twice that of the next larger size and one-half that of the next smaller size. There is, therefore, no difficulty in remembering this column. In the second division of the table the wires are ten sizes smaller than those in the first division; thus, No. 11 corresponds to No. 1 and the resistance is ten times as great. In the third division of the table the wires are ten sizes larger than those in the first division; thus No. 0 corresponds with No. 10 and the resistance is one-tenth as great:

Size.	Ohms.	Size.	Ohms.	Size.	Ohms.
No. 1	.125	No. 11	1.25	No. 0000	.0001
No. 4	.25	No. 14	2.5	No. 0	.1
No. 7	.5	No. 17	5	No. 3	.3
No. 10	1	No. 20	10	No. 6	.6
No. 13	2	No. 23	20	No. 9	.9
No. 16	4	No. 26	40	No. 12	1.2
No. 19	8	No. 29	80	No. 15	1.5
No. 22	16	No. 32	160	No. 18	1.8
No. 25	32	No. 35	320	No. 21	2.1

From this table several new relations may be observed.

If the wire is one size smaller, the resistance is 25% greater. For example: Compare No. 11 with No. 10, No. 12 with No. 11, No. 13 with No. 12, etc.

If the wire is two sizes smaller, the resistance is 60% greater. For example: Compare No. 12 with No. 10, No. 16 with No. 14, No. 15 with No. 13.

If the wire is one size larger, the resistance is 80% that of the smaller wire. For example: Compare No. 9 with No. 10, No. 10 with No. 11.

If the wire is two sizes larger, the resistance is 63% of that of the smaller wire. For example: Compare No. 11 with No. 13, No. 4 with No. 6.

From the foregoing the following are the ratios of resistance between wires of consecutive sizes:

.50, .63, .80, 1.00, 1.25, 1.60, 2.00.

**WEIGHT.**—The weight of a wire is inversely proportional to its resistance. Therefore, the foregoing relations are the same for weight as for resistance, excepting that the weights increase as the size of the wire increases, instead of diminishing. The weights of successive sizes of wire, therefore, bear the following relation, beginning with the smaller wire:

.50, .63, .80, 1.00, 1.25, 1.60, 2.00.

If the weight of any size of wire is known, it is therefore seen that the weight of the next larger size is 25% greater; the weight of the second larger size is 60% and the weight of the third larger size is double; also, the weight of the sixth larger size will be four times as great, and the weight of the tenth larger size will be ten times as great.

The weight of 1000 feet of No. 10 copper wire is 31.4 pounds. Therefore, the weight of No. 7 wire is 62.8 pounds; the weight of No. 0 wire is 314 pounds. The weight of No. 5 wire is 100 pounds per thousand feet, which is a convenient figure to remember. The weight

of No. 2 wire is, therefore, 200 pounds, and the weight of No. 00 wire is 400 pounds.

**AREA.**—The area of No. 10 wire is approximately 10,000 circular mils (more precisely 10,380). The area is proportional to the weight. The area of No. 7 wire is, therefore, about 20,000 circular mils; of No. 0 wire, 100,000, and of No. 0000 wire 200,000. The precise area of No. 10 wire is 10,380 circular mils. Taking this figure for easy calculation as 10,400 and following the process above indicated, the area of No. 0000 wire is found to be 208,000, which is very nearly 211,600, the figure in the wire table.

**DIAMETER.**—The diameter of No. 10 wire is approximately 0.10 inch (more precisely 0.102 inch). The diameters follow the same ratio as the circular mils and weights, except that this ratio applies to alternate sizes. Therefore, the sixth smaller size has half the diameter and the twentieth smaller size has one-tenth the diameter. Therefore, as No. 10 is 0.10 inch, No. 16 is 0.05 inch and No. 30 is 0.01 inch; also, No. 4 is 0.20 inch and No. 000 is 0.40 inch; also, No. 0 (two sizes smaller than No. 000) has 80% less diameter, or 0.32 inch. No. 00, lying between these sizes, may be presumed to be about 10% less than No. 000, or .36 inch; the diameter given in the wire table is 0.3648.

Reference to a complete wire table will show that the figures in the above examples and other figures which may be determined in the same way are correct within a few per cent. A little practice in mental arithmetic will enable anyone to determine the approximate weight and resistance of wire of any size.

**SUMMARY.**—The things to be remembered regarding B. & S. gauge copper wire are the following:

A wire which is three sizes larger than another wire has half the resistance, twice the weight and twice the area. A wire which is ten sizes larger than another wire has one-tenth the resistance, ten times the weight and ten times the area.

No. 10 wire is 0.10 inch in diameter (more precisely 0.102); it has an area of 10,000 circular mils (more precisely 10,380); it has a resistance of 1 ohm per thousand feet at 20° Centigrade (68° Fahrenheit), and weighs 32 pounds (more precisely 31.4 pounds) per thousand feet.

The weight of 1000 feet of No. 5 wire is 100 pounds. The relative values of resistance (for decreasing sizes) and of weight and area (for increasing sizes) for consecutive sizes are:

.50, .63, .80, 1.00, 1.25, 1.60, 2.00.

The relative values of the diameters of alternate sizes of wire are:

.50, .63, .80, 1.00, 1.25, 1.60, 2.00.

**CIRCULAR MILS.**—Conductors of large size are usually specified in circular mils. For example, 500,000 circular mils, 750,000 circular mils.

As No. 10 wire has approximately 10,000 circular mils and a resistance of 1 ohm per thousand feet, and as the length of a wire which has a given resistance is proportional to its area, it follows therefore that the length in feet of a copper conductor having a resistance of 1 ohm may be found by dropping one cipher from the number expressing its circular mils—for example, No. 10 wire has 10,000 circular mils and a resistance of 1 ohm per 1000 feet; a 300,000 circular mil conductor has a resistance of 1 ohm per 30,000 feet and a 1,000,000 circular mil conductor has a resistance of 1 ohm per 100,000 feet. The weight of a given length is proportional to the area; therefore, the weight of a conductor having 500,000 circular mils is greater than that of No. 10 wire in the same ratio that its area is greater. Five hundred thousand circular mils is fifty times that of No. 10 wire, or approximately fifty times 32 pounds, which equals 1600 pounds per thousand feet. In this way the approximate characteristics of copper conductors may be quickly ascertained.

To find resistance, drop one cypher from the number of circular mils; the result is the number of feet per ohm.

To find weight, drop four cyphers from the number of circular mils and multiply by the weight of No. 10 wire.

## THE PROSPECTOR.

The rock samples from Bearmouth, Mont., are: No. 1, clay of apparently good quality; it should be sent to manufacturers of pottery, tiles, etc., to ascertain its value locally; fire clay is distinguished from brick clay, etc., by the almost complete absence of iron, lime and alkalis; if over 4% of impurities are present the clay loses its refractory properties. No. 2 is a fragment of rock crystal-quartz.

The rocks from Clarksville, Cal., marked E. W. S., are: No. 1 is diabase. No. 2 is probably syenite; the feldspars are much altered and are opaque, which makes optical determination difficult.

The red rock from Pearl, Idaho, is a consolidated volcanic tuff, the feldspathic constituents of which are altered to clay.

\*Trans. Elec. Club Jour.

## MINING SUMMARY.

Specialty Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

The production of quicksilver in 1904 is estimated at 3391 tons, not including the output of Mexico and Russia, of which no statistics have been received as yet. In 1903 these countries yielded 190 and 362 tons, respectively. The production in 1904 of the United States, Spain, Austria, and Italy were 1480 tons, 1020 tons, 536 tons, and 355 tons, respectively. Counting the output of Mexico and Russia, the world's production for 1904 will probably amount to 4000 tons.

### ALASKA.

The Canada Klondike Co. is putting in a bucket dredger 40 miles above Dawson.

T. S. Nowell has sold to B. Thane and associates claims owned by the Nowells, the Borsors Bay M. & M. Co. and the Northern Belle G. M. Co., including the Eureka, Johnson and other mines near Juneau. The 40-stamp mill on the Eureka property is to be equipped with concentrators. A body of rich ore has just been struck in the shaft of the Jualin mine, Berners bay, at the 160-foot level.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The Calumet and Cochise group, or the Cunningham group, near Bisbee, has been sold to the Warron Realty & Development Co., one of the Bonanza Circle enterprises. Bisbee, May 29.

The Promontory mining claims at Bisbee have been sold to Eastern capitalists for \$60,000. The new owners will develop them and make surface improvements.

The drift on the 500-foot level of the Shattuck mine at Bisbee is in 140 feet. The shaft is down 665 feet. Two gold bars valued at \$700 are the product of six days' operation of the 5-stamp mill of the Gold Nugget M. Co., 4 miles southeast of Bisbee. New stamps are to be added to the mine and concentrators put in. Two new hoists are also to be added.

#### Gila County.

The Con. M. & Dev. Co. is preparing to begin work on their property, 9 miles west of Globe, at the head of Arkansas gulch. R. Fleming is having a shaft sunk on a claim adjoining the Geneva mine, owned by the Old Dominion Co. of Globe. The shaft is down 70 feet.

#### Graham County.

The Arizona Copper Co. has started work on a tunnel through International hill to connect the Humboldt mine at Morenci with the proposed site for the new concentrator which will be built on the old Detroit mine opposite the smelting plant of the Detroit Copper M. Co. The new concentrator will be capable of handling 700 tons daily and will be connected with the Humboldt mine by electric motors, which will convey the ore to the mill. The tailings will be delivered into a series of settling tanks and dried, after which they will be hauled to the mines and dumped into the waste pits, thus overcoming the additional damage to the rivers below. The construction of the plant will be under the supervision of C. D. Clark.

The Arizona Copper Co. at Clifton have three Hancock jigs in operation and are preparing to put in two more. One of the jigs is said to be handling 800 tons of ore daily. The jigs have increased the capacity of the plant 300 tons daily. Geo. Fraser, superintendent of the smelting department of the A. C. Co., has commenced a new tailings bin on the bank of the river where the old bins stood before the flood. The bins will have a solid rock foundation.

#### Mohave County.

L. Hoffman, superintendent and one of the owners of the Samoa mine in the Central range, 5 miles east of Chloride, has increased the working force of his mine and will begin operations on the Fourth of March claim adjoining on the east. The Yucca M. Co., in San Francisco district, are down 516 feet in their working shaft, in 3 feet of ore on which the mill is being run. The directors have agreed to put in new and better machinery in both mine and mill and the development of the property below the 500-foot level. Air drills will be put in and an up-to-date plant put in the mill.

E. B. Payne has opened up silver ore on his Roger Boy mine, 5 miles northeast of Chloride.

#### Pinal County.

Sinking has been resumed at the Buckeye shaft of the Troy-Manhattan Co. at Troy. The shaft is to be carried from the present 200 to the 500-foot level.

A successful run of ore is said to have been made through the Monarch 10-stamp mill, belonging to the Desert Queen G. M. Co. in Casa Grande district. The vein is a fissure in limestone and is opened up by a 60-foot shaft. The company is planning to put in a 40-ton cyanide plant for a recovery of the fine gold in the mill tailings.

#### Yavapai County.

(Special Correspondence).—At the Sterling mine in Big Bug district, pumps are clearing the mine from water and development work will soon be taken up. The main shaft is down 470 feet and drifts are being run both ways on ore.

Big Bug, May 30.

A rich strike has been made in the properties belonging to the Oro Con. Co., on the west side of Kirkland valley. The ore was broken while sinking in the 180-foot shaft. The shaft will be sunk to a depth of 300 feet and cross-cutting started.

A dam is to be built in the canyon below the Rincon mine, near Prescott, to store water for milling purposes. The dam will be 180 feet long, 22 feet wide at the base and 4 feet wide at the top. The capacity will be 400,000 gallons. The Pittsburg-Jerome Copper Co., 3 miles southwest of the United Verde at Jerome, is making

preparations to put in a reduction plant. C. E. Butler, manager for the company who purchased the Czarnowski Do Amond and Patterson claims, near Martinez, is making preparations for work at the mine.

### CALIFORNIA.

#### Amador County.

The Bay State mine, near Plymouth, is closed down at present. W. W. Worthing is superintendent. P. B. Aikon, interested in the Climax mine, near Pine Grove, reports that the 5-stamp mill has been disposed of and a 20-stamp mill will be put in. The Burlington mine, near Sutter Creek, is putting in machinery from the Stuckton Hill mine, in Calaveras county.

#### Butte County.

It is reported that the rock piles turned up by the dredgers near Oroville will again be turned over in the search for gold. Gold is believed to exist in paying quantities below hardpan, and it is said that before many months drills will be at work prospecting to a much greater depth than the present dredgers are working.

#### Calaveras County.

At the South Bank, on Indian creek, the excavation for the mill is nearly completed. The shaft is to be sunk another 100 feet.

The North Star M. Co., near Mokelumne Hill, intends doing extensive work soon. J. C. Kemp Van Ee, the manager, intends putting in electric machinery to operate the works. The drain tunnel, which is 2100 feet in length, 10 feet wide at the bottom, 8 feet on top and 7 feet high, with a double track, will be equipped with electric motors, and each motor will pull a train of six cars, holding two tons each. The rails are thirty-five pounds in weight. The gravel will be worked by a cylinder mill and 800 tons per twenty-four hours will be handled.

#### El Dorado County.

The Miners' Association of El Dorado county, A. B. Gould of Placerville president, has appointed a committee of reference to whom all inquiries concerning the mines of El Dorado county can be referred. This is hoped to expose certain wildcat schemes recently advertised. At the Rio Vista copper mine, near Fairplay, they are down 400 feet and 140 feet below the bed of the river, where they are drifting. A new dam and flume will be built to insure a fall of 250 feet.

#### Kern County.

It is reported that the Yellow Aster Company at Randsburg is to put in 170 more stamps, making 300 in all.

#### Nevada County.

The Wright and Bailey claims, on the Middle Yuba, near Sweetland, have been sold to a New York company by O. Phippen of Forest City, H. Daniels of Nevada City and Mrs. Cross of North San Juan. The ledge is said to be 125 feet wide and can be easily worked from near the river. The company intends to quarry it out from wall to wall, starting on the river and working up. It is understood that the mill will have a capacity of 500 tons daily. In addition, a cyanide plant will be built. The machinery will be operated by electric power.

#### San Diego County.

(Special Correspondence).—In Pine Valley district, about 10 miles east of Descanso P. O., the Noble mines have been operated for several years. The veins occur in mica schist and in places are high grade in gold values. Lead ores rich in gold also are found here. A recent development is that of a vein in gneiss. The vein is about 2 feet wide and it carries shoots or lenses of mispickel which is auriferous. In places the vein is 8 to 10 feet wide and outcrops for several hundred feet. It is accompanied by a dike rock. This is the first development of any considerable quantity of mispickel in these mines. This particular vein is about 200 feet distant from the contact of granite and schist. A promising copper prospect has also been discovered recently on the divide between Pine valley and Cottonwood creek, the iron gossan of which is reported to assay 10% copper and \$4 gold per ton.

Descanso, May 28.

#### Shasta County.

The tramway at the Sunny Hill mine at Igo is completed.

The aerial tramway that will transport ore from the Mammoth mine to the smelter at Kennett will be 12,835 feet long. The mine is 2205 feet higher than the smelter. On the tram line there will be thirty-eight towers for the support of the cable-line. The highest of these will be 95 feet. There will be two tension stations and one transfer station. In the Mammoth mine 120 miners are employed blocking out ore.

#### Sierra County.

Extra men are employed on the Sierra Buttes mine at Sierra City, grading and getting ready to put forty stamps in the old No. 9 mill, also an addition to the cyanide plant which has been running successfully since last fall. The Mountain mine, above Sierra City, has started with a small force repairing the tramway which was buried last fall. More men will be put on as soon as the roads are in condition to haul lumber from Sierra valley. At the Keystone mine, near Sierra City, they are raising on the vein from the lower tunnel to tap the upper works. The raise is up 360 feet with 80 feet more to go. Repair work is being done in the tunnels in the upper workings. At the Marguerite mine, near Sierra City, they are pumping out the old shaft. The new company has put in two new pumps. The same company is also operating the Northern Belle. R. Phelan has men building a bridge across the Yuba river at the Big Avalanche ravine. He also has men grading for a 5-stamp mill on the Roman mine, and several working on the Commodore, near Sierra City. At the Pride mine, above Sierra City, they are running a prospect drift to determine the value of the large gravel channel, as it is thought by the owners that the mine will pay better for drifting than by hydraulic mining and at less expense. Hayden & Kish are making preparations to start the Gold Ridge, near Sierra City. There is some talk of starting the Butte Saddle and Chipps mines this season. Berger & Winters have bonded the Young

America mine, near Sierra City, and will begin operations immediately.

C. S. Weisenborger will put up the 5-stamp mill on the Two Counties mine, south of Alleghany. J. M. Harper, superintendent of the Diadem quartz mine and the Columbia Channel gravel mine, at Forest City, has men repairing the Diadem drain tunnel and will pump out the 250-foot shaft and reopen the property.

#### Siskiyou County.

J. R. Wade, of the dredger at Callahan, reports that he will close down for a week, to add more buckets to the ladder in order to reach the bedrock. A rich strike is reported from the Wild Irishman claims, near Cecilville, owned by H. Bowerman. At the McKean mine, near Callahan, forty men are at work. The cyanide plant is kept running constantly. The Siskiyou Electric Light & Power Co. is preparing to put in new machinery at Fall Creek, and to increase the plant 1500 H. P. The Scott River Advance says that the King Solomon mine, near Cecilville, will resume work before the year is over. As soon as a wagon road is finished, the company will put in machinery that will enable them to handle 100 tons of ore daily. They expect to put in an electric power plant in the Salmon river for generating the power. A new sawmill will be built and, after the lumber is sawed, they will put up a milling plant, boarding house and bunk house. A lower tunnel is to be run. The Salmon River Co. of Cecilville are extending their flumes from the Summerville property down to the Petersburg placer mines on South Fork. They are sawing lumber and expect to commence their buildings soon and be ready to mine by October. Henderson, Heighy & Marcus have a lease from the Salmon River Co. and are mining the gravel near the Jordan place on South Fork. They have two 6-inch giants and plenty of water operating night and day on a good bank of gravel. S. Conzetti is operating his giants on the Canyon claim, near Cecilville. Smithson & Roberts, of the Knownothing mine at Gilt, are running in their lower tunnel to tap the vein. Superintendent Taggart, of the Red Hill M. Co., has men working at the Red Hill placer claim on South Fork, also at the sawmill to get out lumber for a new flume to be built from Knownothing creek on to the Missouri Bar claim, above the Forks of Salmon. A. Ball expects to resume work on Methodist creek, near Gilt, by June 1. Godfrey Bros. will start their quartz mill, near Gilt. The Gold Run M. Co. of Gilt are doing development work in their upper tunnel.

The Jenny Lind mines, in the Humbug mining district, near Yreka, has been sold by O. Lamson and J. F. Van Saun to M. B. Newcomb of Oat Hill, Napa county.

#### Tehama County.

(Special Correspondence).—C. M. Basler of the Basler M. & D. Co. reports a good ore body at their property at Lowry P. O.

#### Trinity County.

D. C. Dedrich of Junction City and W. E. Livesley of Reno, Nev., have bonded the Lookout quartz mine, near Indian Creek, from M. Collins. Dedrich has charge of work at the mine. J. H. Porter, manager of the Fairview mine at Papoose, reports that the company is running thirty of the forty stamps in the mill. Work will be begun on the Oriole mine on Indian creek, owned by Paulsen & Collins Bros.

#### Tuolumne County.

(Special Correspondence).—The Sierra Railroad has engineers in the field running a preliminary survey to extend their line to Sugar Pine and the Jawbone country. This will open up to prospectors a desirable field. It is proposed to reopen the old Dead Horse mine, on Turnback creek, at Carters. It is proposed to drive a diamond drill hole from the tunnel into the old workings and drain off the water through it. Superintendent N. Carmichael of the Confidence mine, 4 miles northeast of Soulsbyville, states that if that mine was sold it would close down until new machinery could be put in. If not, it would probably be run as at present until fall, and then the machinery would be pulled and the mine closed indefinitely.

Carters, May 31.

The Rawhide mine, at Jamestown, has been closed down while the shaft is being repaired and retimbered. Water has caused the shaft to cave, and it is said the pumps are unable to keep the mine clear. Skips have been used for bailing, yet it is reported that the 1600-foot shaft is filled with water to the 1000-foot level.

It is reported that work is to be resumed at the Republic mine, near Sonora. The copper property on Mitchell ranch, near Cooperstown, has been unwatered and sampled. J. A. E. H. and H. McMahon have bonded to I. Le Mahieu, one-half interest in the Fair Oaks mine, in Confidence district, between the Mustang and Butter Cup mining claims, in consideration of which he agrees to build and equip a 5-stamp mill, complete with amalgamators, ore bins, concentrators, etc., said mill to be used to crush rock from the Mustang and Fair Oaks mines. At the Eagle-Shawmut mine near Chinese Camp nearly 250 men are employed and the 100 stamps are dropping steadily. The chlorination plant across the creek keeps the aerial tramway in operation transporting the concentrates from the mill. It is reported that for the last month the total expense per ton for extracting and reducing ores was \$1.46. C. E. Uren is manager. The shaft of the Republican mine at Jacksonville is down 650 feet and ore for the 20-stamp mill is being taken from the 200 and 300-foot levels. T. H. McGovern is superintendent. Manager W. J. McCray has put in an 8-drill compressor at the Clie mine at Jacksonville and will start sinking in the shaft. The 10-stamp mill will not be started for a time. G. Chamberlain is superintendent.

### COLORADO.

#### Boulder County.

(Special Correspondence).—The Strong-Trojan M. & L. Co. has been organized and will start operating the old Trojan on Sugar Loaf mountain. Salina, May 29.

(Special Correspondence).—The Chicago, Bird's Nest and Enterprise mines have started hauling ore from the

mines to the railroad for shipment. The roads have been in such shape up till the present time that they have been unable to get the ore down from the mines. The Colorado & Northwestern is operating its trains into Eldora and Ward. It is understood they are extending the third rail from Boulder into Denver over the Colorado & Southern, and will be operating their trains out of Denver. The Colorado & Northwestern is narrow gauge and in order to enter Denver they are obliged to lay a third rail.

Eldora, May 29.

(Special Correspondence).—The Governor Routt mine, W. C. Austin manager, is operating at the 117-foot level and taking out ore averaging from \$30 to \$35 per ton. The shaft is down 160 feet.

Sunset, May 28.

(Special Correspondence).—North of Ward, on Little Jim creek, the Myrtle M. Co. is overhauling the 50-ton mill. When in operation the ore will pass through the rock breaker, then to the roughing rolls and over a rotary screen, which takes out all the ore to 20 mesh, the oversize going through the finishing rolls into the bin and through the Motter roaster, from the roaster into the storage bin, and from there to the cyanide tanks. It is expected that the mill will be in operation by June 1. A. T. Rautenberg is manager and R. C. Morrison mill superintendent. The shaft on the Myrtle is down 340 feet; also a tunnel 900 feet in intersects the shaft. The ore from the tunnel level is said to average \$8 per ton. The Utica Hill G. M. Co. are overhauling the Quiglyville mill and will operate the same on ore from their own mine. They have put in ten stamps and plates; also have two Wilfley tables and two vanners. They have 200 tons in the bins awaiting treatment. The mine is 2 miles from the mill. J. J. McKinry is president and manager. The smelting ore averages \$70 to \$120, mill dirt \$15 to \$20 per ton. The Ward Strugler G. M. Co., 3 miles north of Ward, is doing development work in the mine and putting the mill in shape for operation. The ore after being hoisted to the surface is trammed to the mill, where it is handled automatically. The mill when operating will have a capacity of forty to fifty tons per twenty-four hours. When running full capacity they will employ thirty-five men in the mine and mill and have a daily output from the mine of sixty tons. G. M. Mitchell is manager. The mill is on the south fork of the St. Vrain river. The B. & M. mine is under lease to G. A. Kline & Co., who are operating at the third and fourth levels and shipping three to four cars of ore per month. They expect to put machine drills at work shortly and do some prospecting and development work on the 500-foot level. Ed. Jones and associates have a lease on the No. 5 mine and started operations. As soon as they draw the water from the shaft they expect to be able to produce ore. The shaft is down 170 feet.

Ward, May 29.

(Special Correspondence).—The closing down of the smelter at Golden will have a bad effect on the shipper from this county, as a large number were already making shipments and others preparing to start operations. The treatment charges were low enough to permit shipments being made of ore that heretofore was thrown over the dump or left in the ground.

Boulder, May 28.

Manager Lake of the Boulder County mine says that the tunnel which will connect the company's mine and mill has been driven 2800 feet and is within 500 feet of the workings. The bore is being driven at the rate of 200 feet a month.

#### Clear Creek County.

The Waldorf Co. expects to have the mill at the Stevens mine, near Georgetown, in operation soon. The close-down was caused by a lack of water to run through the winter. On account of a lack of early winter snows in this region everything froze. To obviate this, provisions will be made during the summer to insure sufficient water and power to run the mill the entire winter.

Work has been started on the Arapahoe claims in the Argentine district by O. Hoffman and C. Gleen. The Democrat Mountain M. Co., a reorganization of the Kelly tunnel holdings on the east side of the mountain, is putting in a raise from the Bonanza tunnel level to connect with the workings now being carried forward on the Edgar lode. The ore body on the Edgar measures 18 inches in thickness, but according to the dip of the vein a junction of the Edgar, Rogers and Jordan lodes will be reached within another 50 feet of sinking. The Headlight shaft, on the American Sisters property, on Silver creek, above Georgetown, is being sunk another 150 feet. This shaft is down 190 feet and, according to surveys recently made, the ore shoot will be reached inside of another 100 feet. This work is being started to cut under the old workings at an increased depth. A compressor, boiler and engine have been put in. The American Sisters property is being developed by the American Sisters Leasing Co., a corporation composed of Georgetown men, with J. J. White and H. J. Crist as managers. Ground is being broken for the New Era mill at the base of Saxon mountain. This mill will have a capacity of 100 tons daily. C. Dubois of Denver has charge of the construction work. Manager Shepard states that finances are now in the treasury for the carrying out of all plans both for the New Era mill and also for the development of the Anglo-Saxon mines. A tramway has been completed which runs from the Saxon-Extension tunnel to the base of the mountain. Work on the Mazepa property on Democrat mountain is pushed, and it is expected to cut the Mazepa lode within another 100 feet. Steady shipments are being made from the Santiago. Shipments from the Lebanon tunnel near Georgetown have been begun by Maxton & Storms, who hold the property under bond and lease. It is understood that Maxton & Storms will begin work on the construction of a 50-ton concentrating mill.

The Colorado & Southern Railway Co. has ordered that, except where otherwise specifically provided, the minimum weight on ore and concentrates between all points in the Clear Creek district will be the marked capacity of the car, to be effective June 1, 1905. This means that a shipper sending ten tons will pay freight

on fourteen or more tons, according to the marked capacity.

A rich strike is said to have been made in the Harris lode, in the Argentine district. The streak of ore measured from 1 to 4 inches in thickness and reported assay values give 22,000 ounces in silver to the ton. The strike was made by W. Farragher, who has been operating the property under lease for several months. The Harris is near the Continental divide and is being developed by a tunnel, which is in over 200 feet. The Harris lode is owned by P. J. R. Manogold and T. Harris of Georgetown and A. Hammer of Chicago. The Crow Foot drift in Griffith mountain, near Silver Plume, is in 1800 feet. The Centennial mine, owned by D. Kennedy, in Georgetown, has opened an ore body in drifting from the fifth level. A. Santa has given a contract for driving the crosscut tunnel on the Big Blue mine an additional 100 feet. This property is on Saxon-Extension mountain, near Georgetown, and the crosscut is in 905 feet. The Hazelton-Santiago M. & T. Co. has let a contract for a 40-ton concentrating mill on its property in Argentine district, above Georgetown. The Allan mill at Idaho Springs has been started on ores from the Cardigan mine, above the Stanley. Metty Bros. have the mill under lease.

#### Custer County.

The Bassick at Querida is being worked under the management of C. E. Anderson. The new shaft is 1800 feet deep and connected with the old one, which is 1500 feet down, by sixteen levels. The entire property is worked by leasers, who do the development and extract the ore, sending the high grade to the smelters direct and the low grade to the Lacy concentrator at Wickliffe. The crater of the Bassick has been cut by a cross-cut for 700 feet east and west, and much workable ore exposed. To the north and south it extends for half a mile. The company's mill, which was destroyed by fire last year, will be replaced by two new ones during the present year.

#### Gilpin County.

Semans & Edwards of Bald mountain have leased the Aetna-Kent mine in Nevada district from J. A. Thatcher of Denver. Iowa parties will put in a 60 H. P. boiler on the Gauntlet mine on the east end of Quartz hill, near Central City, and will deepen their shaft from the 500-foot level.

The Pozo mine in Nevada gulch is shipping three cars of concentrates and ores each month to the Colorado Zinc Co. of Denver. It is owned by W. J. Lewis & Son of Central City and is being worked under a lease and bond by Denver parties. President J. P. Cappeau of the Russell M. Co., operating in Russell district, is making arrangements to resume mining about June 1. It is expected that machinery will be put on the shaft.

President J. C. Nixon of the Roderick Dhu Gold Mines Co., near Central City, says that the company is arranging for active operation of the entire property. No attempt at production will be made for six months, only the ores taken out in development being shipped. The company will discontinue leasing in the Protection shaft workings, which are down 557 feet. The main shaft on the Roderick Dhu is down 300 feet, this shaft being sunk through the old workings to virgin ground, which they expect to strike at a depth of 400 feet, and they intend to sink several hundred feet in order to open up new ground. The Quartz hill tunnel drains the property to a depth of 600 feet and the Newhouse tunnel, which will run 300 feet east of the property and will cut it at a depth of 1800 feet, is expected to also drain the surrounding territory. Leasers have been taking out good ores from the 334-foot level of the Protection mine. Eilmann & Co. are working their lease on the Susan Mary mine near Lake gulch, and intend to put up a whim and sink deeper on the shaft north of the main workings. Persig & Co. of Black Hawk are sinking a shaft on the Plymouth claim, an extension of the Carr on Bobtail hill, and will put up a small plant of machinery if their prospects hold out. Sinking operations are being carried on with day and night shifts at the Caledonia property in Lake district by the New National Tunnel M. Co. The main shaft is down 500 feet. They intend to sink an additional 300 feet, which will bring them to the level of their tunnel workings that are coming in from North Clear creek, and will mean the future handling of all ores as soon as the connections are made, giving them drainage as well as improved ventilation facilities. G. W. Adams of Central City is manager. The Justice mine in lower Russell district is being operated under a lease and bond by J. F. Stanish of Central City. Operations have been temporarily suspended at the Alva Adams property in Russell gulch on account of the large amount of surface water which that property is making. Sinking operations have been suspended at the Pittsburg shaft of the Cashier G. M. & R. Co. in Russell district, near Central City, the shaft being down 720 feet. The 700 east level has been started. Water difficulties stopped sinking in the winzes below the 600-foot east level, which will be remedied effectively as soon as the 700-foot level is in far enough to drain off the water. B. L. Campbell is superintendent and W. Auger foreman. Mitchell & Sons are drifting west at a depth of 360 feet in their Gulch mine in Lake district. They are also crosscutting at a depth of 80 feet. The Town Topics G. M. Co. intends to continue the East Notaway shaft in the Russell district to a depth of 1000 feet. Sinking has stopped for some time on account of bad air, and connections are to be made from the bottom level west to the 555 level, after which sinking operations will be resumed. T. Martin is superintendent at the mine and S. A. Josephi of Denver president and manager. A rich strike is reported in the 200-foot level of the Eldorado mine in Russell district, being worked by the Eldorado M. Co., S. T. Harris, manager. It is reported that a larger plant of machinery and new shaft building is to be put up on the property.

#### Gunnison County.

The Sunlight G. M. Co. has opened rich ore in its tunnel on Beacon mountain, near Sherrod. The tunnel is in 200 feet and the vein was opened in a drift from the same. W. M. Beacon, superintendent of the Gunnison line of the Colorado & Southern, and J. M. Herbert are interested. The N. B. C. Mining Co. has let a con-

tract to drive a tunnel into Brittle Silver mountain 500 feet. The Nannie Sherrod and Pay Well Mining Companies expect to resume operations soon. The Buena Vista M. Co. is making preparations to do extensive work on its properties at Hancock. The company is running a long tunnel into Mount Chapman. The Camilla Co. will resume operations on its tunnel into Pomeroy mountain north of Hancock.

The Spring Valley G. M. & R. Co. has a lease and bond on the Midland mine, 12 miles south of Gunnison, and has put men to work. F. Winters is manager. He has started a tunnel to cut the vein 100 feet below the present shaft. The tunnel will be driven 800 feet, giving it 400 feet of depth on the vein.

#### Lake County.

At a depth of 320 feet a body of good sulphide has been opened in the Corona, California gulch, near Leadville.

The Dome claim of the Iron Silver M. Co., on Rock hill, Leadville, has commenced shipping. A new shaft is to be sunk on the Georgia claim to aid in developing the Reindeer on Rock hill, Leadville. On account of the backward season but few placer claims have resumed work, but as the snow is rapidly disappearing the owners of placer ground at Alicante and other sections expect to get to work by June 1. Work has been resumed on the Tom Starr placer, at the foot of Harrison avenue, in California gulch. The Twin Lakes placer is being worked with three hydraulics. It is expected that the ground from Malta down to Hayden, on the Arkansas river, will be worked this season. Last fall the Saguaque G. M. Co. got an option and lease on the ground from opposite the old Union smelter down to Malta, and the terms of the lease were that a dredging machine had to be put in and the ground worked systematically, but it is doubtful if the ground will be worked this season. Sinking has been finished on the Nil Desperandum, on Rock hill, and drifting started in southerly direction. The Last Chance shaft, 500 feet deep, on East Fryer hill, near Leadville, after being idle for two years has resumed work. From the bottom of the shaft a drift will be run east 200 feet to catch the ore shoot that is believed to pass through that part of the property. The work is in charge of B. Dubois.

At the Sunset mine, on the northern slope of Twin Peaks mountain, operated under lease and bond by the Twin Mountain M. & M. Co., with T. Henneberry of Twin Lakes as manager, a new trail will be built to the upper workings, an underground survey will be made in the deep tunnel to locate the ore bodies, and the ore in sight will be extracted and shipped as soon as possible.

#### Larimer County.

It is reported that the Mt. Zirkel property, south of Pearl, is to be pumped out preparatory to examination. The Mt. Zirkel has been idle for two years, and has a well timbered shaft 285 feet in depth. The veins near Pearl occur in fissured zones in the granite-gneiss, the vein filling being altered country rock with variable gold and silver-bearing copper ores associated.

#### Montrose County.

A late dispatch reports a cave-in occurred May 30 in the Gunnison tunnel, one of the largest irrigation projects of the United States Government, entombing twenty-seven workmen, killing at least five men and seriously injuring two, who were pinned under heavy timbers, and would have been drowned but for the efforts of their entombed companions, who improvised a dam to hold back the water which poured into the tunnel for a time. Twenty-one men were rescued uninjured, but exhausted by their experience. They were hoisted with ropes through a shaft which had been sunk 60 feet in less than twenty-four hours. The rescuers worked in three-minute relays until the tunnel was reached. When the heavy timbers of the roof of the tunnel were broken the entombed men were found standing in water above their knees and still working with a will to prevent further disaster, as the soft dirt was constantly sliding. The cave-in occurred beneath the bed of Cedar creek, and was primarily due to the softened earth caused by seepage from the creek.

#### Ouray County.

Near Iron-ton work has been started on the Harrison lode, on Brown mountain, by Dr. Burrows on the Greyhound group in McIntyre gulch, on the Beaver, Belfast and Bellevue, and on the W. C. Davis Minneapolis group. West of Iron Park the Kennedy, Kimball and Lyons are being worked.

#### San Juan County.

Trails to the mines are being opened up and it will soon be possible to transport supplies to many properties which were running short on account of the unusually long winter. In the hills the snow lies at great depth, and it will be fully a month before mining operations can be generally resumed. The Red Mountain Railroad is snowed in. The Silverton Northern line from Eureka to the Animas Forks section is blocked by snow. The snowfall has been very heavy and as a consequence all mining operations in the district have been retarded at least one month. Operations have been resumed on the Tom Moore, north of Silverton, by Manager S. G. Martin. The water supply for the Highland Mary mill, on the ground of the Gold Tunnel & Railway Co., up Cunningham gulch, 8 miles from Silverton, is obtained from a lake 1½ mile farther up the mountain. Owing to the severity of the past winter the pipe line has been cracked by frost, stopping work at the mill until it can be repaired, probably by June 15.

The Mogul M. Co. will build a \$250,000 concentrating plant at Gladstone, 9 miles north of Silverton. The structural part of the new mill will be of concrete and steel and will be equipped with forty stamps, concentrating tables, tube mills for regrinding, etc. The Mogul mines are 2 miles from Gladstone, near the head of Cement creek, and in order to transport the mineral from the mines to the mill an aerial tram line 8000 feet in length will have to be built. The zinc product will require special treatment by magnetic separation.

It is reported that L. Jakes of Grand Junction will operate a custom mill and testing plant at Silverton.

## San Miguel County.

The mines and the 50-ton stamp mill at Ophir Loop, owned by the Ophir Con., have been sold to satisfy the demands of the Mine & Smelter Supply Co. of Denver, by whom it was bid in for the amount of the claims—\$3660 and costs. The mining company will doubtless regain the property in the near future.

## Summit County.

A new hoist and equipment is being put up at the American Flag mine, near Park City. Water has caused a temporary stoppage of work at the 800-foot level of the New York Bonanza at Park City.

C. A. Finding has started work on the Minnie mine, near Breckenridge. The Oro mine, near Breckenridge, is being worked by J. McGarvie.

S. C. Huntington, W. E. Stouffer and J. Bernatchio have taken a contract to sink the Loring shaft, on the Bemrose placer, near Breckenridge, 100 feet deeper. The King Solomon Tunnel Co. at Frisco is putting in air drills to complete the driving of its big tunnel.

## Teller County.

Superintendent R. D. Wattles of the Bull Hill M. & D. Co., working the Crosson property on the Raven hill side of Eclipse gulch, Cripple Creek, is timbering the main shaft from the 300-foot level to the surface, preparatory to taking out ore from the vein recently struck. The Morning M. & L. Co. are straightening the shaft of the Aileen on Guyot hill, Cripple Creek, preparatory to sinking and developing. Lessee Granfield, operating the C. K. & N. property on Beacon hill, Cripple Creek, has a station at the 800-foot level and started drifting to open up the vein system which has been worked in the levels above. Sinking will be resumed until the 900-foot point is reached.

P. G. Conover is starting work on the Janie Dix and the Holmdell claims, at the head of Twelfth street in Goldfield. These claims lie on the Big Bull mountain, which has yielded no ore of consequence, although subjected to surface exploitation at several points. It is reported that the 240-foot three-compartment shaft on the Ocean View, at the northern end of Battle mountain, Cripple Creek, is to be sunk to a depth of 1000 feet. A roaster is to be added to the equipment of the Cripple Creek Cyanide Co., owner of a cyanide mill near Gillett. Manager W. G. Beyerly has been in Chicago buying machinery. J. E. Bergeron has taken a two-year lease on the Lillie mine and the Lucky Friday lode of the Vindicator Co. of Cripple Creek. High-grade ore has been found by L. Inskeep, prospecting the south block of the Agnes property, on the northeast slope of Beacon hill, Cripple Creek. Work is being done on the bottom level at a depth of 100 feet.

At a recent meeting of the Doctor-Jack Pot directors, they accepted a proposition made by McAllister & Gandy to take the mine for a cash consideration of \$75,000, thereby liquidating the company's indebtedness of \$65,000 and leaving \$10,000 cash balance in the treasury of the new company which McAllister & Gandy agree to form. This sale will prevent the foreclosure of the mortgage on the mine in the district court at Cripple Creek. On the Bonnie Nell property, owned by the Merger Co., of Cripple Creek, Manager Storke is sinking to the 1000-foot point from the 600-foot level.

The Exposition Mines Co. of Cripple Creek, operating on the south end of the Burns claim of the Acacia Co., have commenced sinking the shaft an additional 100 feet. Lessee J. Wright, leasing Blocks 240 and 241 of the Stratton-Cripple Creek M. & D. Co.'s estate, has put in a large compressor and will put in several machine drills at once. Block 211 of the John A. Logan mine from the surface down to the 500-foot level has been leased to the Logan M. & L. Co., of which B. P. Anderson, I. Howbert and J. A. Himebaugh are stockholders. Other leases have been granted by the Stratton people on Blocks 170, 171, 172 and 173 of the Longfellow property to R. P. Russell of Cripple Creek and on Block 229 of the Nightingale to G. Ferriek of Cripple Creek. The property of the Black Belle Co., on Beacon hill, Cripple Creek, is being worked by the Cripple Creek Gold Temple M. Co., operating the south 750 feet under lease. As surface water is leaving the property, the management is making arrangements to sink another 100 feet, giving the shaft a depth of 405 feet.

The shaft of the Teutonic, Cripple Creek, is to be sunk 100 feet from the 300-foot level by Duncan & Cam, using machine drills. The Gold Coin Co. will start unwatering the lower level and will open up the extension of the Gold Coin-Dorothy veins. Plans have been made for a compressor and another boiler for the Blue Flag properties on Raven hill, Cripple Creek. The shaft is down 200 feet. J. F. Erisman is president and manager and C. H. McCrew superintendent.

The McKinney Extension G. M. Co., of Anaconda, has put in machinery and is sinking the shaft to the 300-foot level. When the shaft reaches a depth of 100 feet lateral work will be started. Lessee W. P. Dunham, operating under lease blocks 3, 4 and 5 of the Jerry Johnson estate, Cripple Creek, is sinking the shaft 4½x9 feet in the clear, to the 400-foot level. The K. C. Mining Co., operating a part of block 3 of the same property, is east and west from the shaft at a depth of 100 feet.

## IDAHO.

## Ada County.

At a meeting of the directors of the American Exploration Co. at Boise, it was decided to put in a 4-drill air compressor on the Nellie mine, to push the work of driving the crosscut tunnel. The compressor will be run by electric power. The tunnel is in over 200 feet and is expected to cut the vein. As soon as the vein has been cut, a 100-ton cyanide plant will be built.

## Boise County.

Superintendent V. Thorne reports that the shaft on the John Henry group, near Idaho City, was sunk 415 feet in seven months. The shaft has three compartments. F. Day has been foreman. The John Henry and Democrat ledges will be tapped from the 400-foot level, where a station is being cut. J. Sullivan reports that the incline on the Mammoth mine, on Summit Flat, near Idaho City, is down 400 feet and a station is being cut.

## Elmore County.

It is reported that the Providence Investment Co. is preparing to build a 10-stamp mill on its Mountain View property near Pine and to construct an electric plant on the South Boise river, 2 miles from the mine, with a capacity of 400 H. P., sufficient to operate the mill and furnish power for the mine. They expect to have both the mill and the electric plant in operation by Aug. 1. The tunnel of the Mountain View mine is in 500 feet.

## Idaho County.

The State Wagon Road Commission has decided to build the Warren-Big creek wagon road, conditional on the citizens of Weiser and the upper country paying half the cost. The total expense of constructing the road is estimated at \$20,000. The route of the proposed road leads from Warren up Warren creek to its head over the summit to Pony creek, down that stream to the south fork of the Salmon, up the south fork to Elk creek, and up that stream to the Elk creek summit, thence to the Werdenhoff mine on Big creek. It is hoped to start work by June 25.

The Copper King Co., which is operating seven mines on the divide between the west fork of Rapid river and the east fork of Granite creek, in the Seven Devils district, is getting satisfactory results from the development work. A winze is being sunk from the tunnel level on a chute of high-grade ore. The ledge is 15 feet wide and has a paystreak 3 feet wide of hornite ore. The company is building a wagon road from the mine to connect with the Kleinschmidt road to the Peacock mine, and will begin shipments to the Landor smelter as soon as this road is finished; they have drifts opened up on the 500-foot level in the winze. C. McKinnis of Mace is general manager.

F. Brown and F. H. Wood of the Jumbo mine at Buffalo Hump report that the Jumbo, Cracker Jack and Mother Lode No. 2 are working full crews. The Hump is covered by 3 feet of snow. The Jumbo is working forty men. The full battery of twenty-four stamps is running. The chlorination plant is saving 95%. They have contracted for a 50-ton cyaniding plant to treat the tailings from the mill and chlorination plant, and expect to put it up in July. The Crackerjack is working twenty men and running twenty stamps. On the Mother Lode No. 2 thirty men are at work.

## Nez Perce County.

J. M. Edwards, manager of the Ohadi M. & M. Co., expects to put in a 15-ton stamp mill in Garden gulch, 35 miles up the Snake river from Lewiston. Five ledges have been opened on the property.

## Shoshone County.

The Bitter Root Mountain M. Co. is developing six claims on the hill south of the Morning mill, on the south side of the south fork of the Cœur d'Alene river, near Mullan. They have started a crosscut tunnel on the north side of the hill to tap the ledge at a depth of 425 feet; 470 feet of this tunnel has been completed. The company is developing six claims 4 miles from Wallace and is running a crosscut tunnel to open it at depth. F. A. Edgerton of Spokane, Wash., is secretary and manager of the company and C. F. O. Merriam is consulting engineer.

The stockholders of the O. K. Con. M. & M. Co. at Wallace have elected J. W. Flink president and manager, E. Pfister vice-president, A. Matt secretary, E. McIntosh of Kellogg and W. Hoare of Tekoa, Wash., directors. The principal work will be centered upon the Mabel claim. It will require 600 feet of tunnel work to intersect the ore shoot at a depth of 250 feet. The Laclede M. Co. has started up its new compressor near Wallace. Only one machine drill will be used for the present. On the surface and in the upper tunnel the Laclede has a fine shoot of ore which it is now aiming to open at a vertical depth of 200 feet by driving a second crosscut tunnel which is now in 200 feet and is estimated to have 400 feet yet to run to cut the ledge.

Old mining properties in the Cœur d'Alenes that in former days have been numbered among the most prominent mines in the district, but which during the latter days have been practically idle, are now being revived and worked. In the Nine Mile district, near Wallace, the California, the Granite and the Custer are being operated. The California Con. has been acquired by a Pittsburg corporation, and men are employed at the mine and mill. Shipments are being made and development work done. The Granite mine has been taken over by the Success M. Co. During the early days of quartz mining in the Cœur d'Alenes this property was considered among the best. By reason of the prevalence of zinc the ores finally could not be profitably worked and the mine became idle. H. F. Samuels took an option on the property, experimented with the ores, learned that they could be worked by a new process and then organized the Success M. Co. Miners are engaged in development work, and a mill is being built, with a view to saving the zinc values as well as the silver and lead. W. R. Swicegood has a number of miners employed on the Custer.

## Washington County.

C. Green, president and general manager of the Idaho Placer M. Co., whose properties are at Old's Ferry, 12 miles west of Weiser, on Snake river, has launched the new dredger and the machinery will be put in as it arrives. The boat is 80 feet 8 inches long, 30 feet 8 inches wide and 4 feet deep. It is built of Oregon fir.

## MISSOURI.

## Jasper County.

The News-Herald of Joplin reports that the Paragon mine and mill, near Joplin, have resumed operations. J. W. Brooks & Co. are getting out good ore on the Schifferdecker land. The Eden M. Co. is drilling on its lease near Joplin. A steam hoist derrick is being put in at the Chuck Luck mine at Four Corners. In drilling east of Belleville, Campbell & Co. struck a large cave at a depth of 90 feet. The Ross M. Co. is draining its mining land and will start up its new mill. The Togo M. Co. has made an excellent drill strike on the Roh Roy lease, 1 mile south of Villa Heights. F. E. Carringer of Denver and J. Vancil of Joplin have leased 200 acres northwest of Oakland and will do 2000 feet of drilling. Scott, Mooneyham & McCarthy have put in

a steam drill and 2-inch steam pump in their prospect at Smelter Hill. A shaft is being sunk on the Schifferdecker land by Messrs. J. F. and W. M. Meese and G. Pulley and W. A. Moses. A shaft has been begun on a four-lot lease on the Schifferdecker land by N. Wheeler, J. Stenson and C. Keller. The Blatz-Weiner Co. is preparing to sink an air shaft at its diggings on the Hunt land, north of Belleville. Bad air has stopped mining operations there. J. A. Stokes & Co. are down 80 feet with their shaft on the Falace 40-acre tract. Jeffries & Co. have commenced hoisting dirt in their prospect on the adjoining lease.

A. Hardy, Sr., of Webb City, has purchased a mine from the F. M. Sponable M. Co. at Neck City. T. N. Davey, U. Hendrickson, W. H. Phelps and H. C. Cnwgill have purchased from M. A. Moseley a one-fourth interest in eighty acres of land 2 miles south of Webb City. G. H. Davis, manager of the Ozark Lead & Zinc Co., has drained the company's land in the Center creek bottom and will place a large pump. Two mills will be begun on the company's land. W. G. Sheldon, of Cartersville, general manager of the Gilt Edge M. Co. at Diamond, reports that his company has thoroughly drilled the bottom of the drift in its mine and finds that it has at least 15 feet of good ore under present workings. The shaft will be sunk deeper and the new stope taken up. The Missouri Blanket Vein Co. has purchased the Squares & Smith mill near Diamond and will have it moved to their new mine at Wentworth. E. Gilbroath, of Cartersville, has the contract.

## MONTANA.

By a decision by the Secretary of the Interior, thousands of acres of the school land of Montana, including that which is most valuable, are to be preserved to the State. The Secretary holds that these lands claimed by the State for school lands are more valuable for minerals than for agriculture, and though such lands were known to contain minerals prior to the date of the admission of the State into the Union, the lands may be held by the State as school lands, notwithstanding their mineral character, unless they had been located or claimed as mineral land prior to November 8, 1889, and that development of mines subsequent to the admission of the State, though the deposits of mineral were known prior thereto, cannot affect the title of the State to lands donated by act of Congress to the State for the benefit of the public schools.

## Beaverhead County.

The Amalgamated C. Co. is working thirty men on its Indian Queen property on Birch creek, Dillon, under the direction of J. Willoughby. The shaft in the long tunnel is 150 feet deep. A new and larger engine has been ordered. The new shaft is a double compartment and is 800 feet from the mouth of the tunnel. Four men are extracting ore from the old workings.

## Deer Lodge County.

The Cable Lease M. Co. has interested capital in its property, 17 miles west of Anaconda. The workings of the Cable are being drained. The tunnel level is 240 feet below the outcrop. In addition to the work on the Cable, the company is sinking a shaft on the Royal Charter and is down 65 feet. The mill will not be started until there is ore enough in sight to keep it running steadily.

## Fergus County.

Superintendent H. H. Lang of the Kendall, at Kendall, states that rapid progress is being made in constructing the cement foundation for the hoist that is to be used in sinking the new compartment shaft.

## Jefferson County.

It is reported that an English company, under the direction of Wm. Brazenall, expects to start dredging operations in the Jefferson river, near Jefferson island.

## Madison County.

The Mammoth M. Co. at Mammoth is employing twenty-seven men and expects to increase the number to seventy-five during the summer. This property owns its own electric plant, furnished from the waters of South Boulder. Compressed air drills are used in driving a 3000-foot tunnel, which is being run to tap the ore bodies at a depth of 1500 feet, on a level with the mill. The Cliff mine at Mammoth, owned by A. Laden and others, is under bond and lease to Seattle parties, who are driving a 400-foot tunnel to develop the ore deposits at depth.

The shaft of the West Colusa at Butte is down 1600 feet and a station is being cut at the bottom. The Blackrock Co. at Butte will sink from the 450-foot to the 550-foot level.

It is reported that the Watseca M. Co. at Rochester will cyanide its tailings dumps.

At the Revenue mine, on Richmond Flat, near Pony, there are 48 miners working, 30 leasers and 18 men, employed in the mill and mine by the company. The company buys the ore from the leasers and treats them in their mill. The ore is treated by the cyanide process. The mill has a capacity of 75 tons per day. R. C. Knox is superintendent, A. Shay is foreman of the mill, and E. Williams foreman of the mine.

## Park County.

J. Hall and R. L. Morton report high-grade ore in the Bi-Metallic mine of the Crown Butte group at Cooke. The ore carries values in gold, silver, lead, copper and bismuth.

H. G. Merry, manager of the Montana Coal & Coke Co. at Aldridge and Electric, has made satisfactory arrangements with the striking miners and work is being gradually resumed.

## Silver Bow County.

The Leadville M. & S. Co. has started work 18 miles north of Butte, under the direction of A. Cottrell.

## NEVADA.

## Elko County.

Plans have been completed for the 1000-ton concentrator of the Nevada Con. C. Co. at Ely. It is expected that the railroad from Toana to Ely will be completed by September 1.

## Esmeralda County.

At Silver Peak the mill of the Mohawk-Alpine Co. is running night and day. J. Chiatovich has started his

mill.—In the Palmetto range, southwest of Silver Peak, several properties are being opened up.

#### Lander County.

The Austin G. M. Co. has been formed with Wm. Easton of Austin as president and T. H. Dalton of Austin as secretary and treasurer to work the Last Choice mine, 1 mile southwest of Austin.—L. D. Gordon has leased F. Pedroncini's interests in the McManus-Pedroncini mine near Marshall canyon near Austin, and McManus & Gordon will put men to work taking out ore. Ore is being shipped from the New York canyon mine, at Battle mountain, Mont., by Superintendent R. Watt.

(Special Correspondence).—There is some excitement in the camp of Bullion, 20 miles south of Beowawe. C. Montgomery and A. Catenhaun have struck good values, and are said to have given a bond to the Amalgamated C. Co., Butte, Mont., for \$150,000. The new strike is 16 miles northeast of Cortez in Bullion and Clipper canyons near the Eureka-Lander county line. Battle Mountain, May 31.

#### Lincoln County.

The Gold Coin M. Co. is operating the Sazerac and Vinona groups at Dupont, 12 miles from Searchlight. C. Anderson is general manager. A gasoline hoist has been placed on the Sazerac.—At the Paralle property, near Searchlight, under the direction of T. D. Forney, sinking in the main shaft has been discontinued.—Work is being rushed on three claims, the Bonanza King, Black Prince and Golden Eagle, 12 miles northwest of Searchlight, in the Crescent range. A shaft is being sunk on the Black Prince which will be put down to water level. J. Bindschadler has charge of the work.

#### Nye County.

F. Griffith and J. W. Montgomery of Los Angeles are at the head of the company intending to put up a 10-stamp mill near Beatty. A contract has been signed to work the ore from the Bullfrog M. Co.'s property. At first the motor power will be gasoline, but later electricity.

The Tonopah Cash Boy M. Co., at Tonopah, has put in a 50 H. P. steam hoisting engine and a 50 H. P. hoiler, capable of sinking to a depth of 1000 feet. L. A. Blakeslee is president and S. Crossley of Los Angeles, Cal., is superintendent.

#### Washoe County.

P. Waldron, Jr., manager of the Harris mine in Jumbo district, 4 miles from Washoe City, reports that company is employing four miners in preliminary work and will soon increase the force. The mine is being worked through a tunnel in 500 feet and from it a shaft has been sunk 400 feet.

The Pittsburg Co., which has bonded the Ora claims, has started work.—H. Hawkes of Colorado Springs, Colo., has an option on the extension group of the Ingalls Dispensia claim, near Olinghouse, of J. C. Effricks, W. Kearney and J. D. Poole.—O. M. Pudor of Houston, Texas, has purchased the No. 2 mine at Olinghouse of Rice & Howard for \$22,500.

#### White Pine County.

M. McGarry intends to resume work at the Cornell lead mine, at Hamilton.

### OREGON.

#### Baker County.

P. Humbert of San Francisco has resumed work at the Cornucopia mine, at Cornucopia, under bond.

The President has created a forest reserve in eastern Oregon to be known as the Wallowa reserve, and is on the Wallowa mountain range, which forms the dividing line between Baker and Wallowa counties, and is in Baker, Wallowa and Union counties. Eagle creek, Cathrine creek, Innaha river and smaller streams are the outlet to the watersheds covered by the reserve. The timber is mostly yellow pine. The Cornucopia, Tenderfoot and Innaha mining districts are affected, as the first two are believed to be entirely within the bounds of the reserve, and the latter's timber and water will come from it.

The Empire group in the Cracker Creek district, near Sumpter, is being developed under the management of A. M. Harris, who has interested Detroit, Mich., capitalists in the mine.—The E. & E. mine at Bourne is preparing to shut down work in the stopes temporarily. Sinking and developing operations will be continued with a smaller force. Greater pumping facilities will be added for handling the increased flow of water that will result from extending the shaft.

W. E. Gifford has found the main ore shoot on the Present Need mine, near Quartzburg, and is shipping to the Sumpter smelter.—Work has been commenced on a lime deposit, near Durkee. A spur is being built from the O. R. & N. main line to the mine and one kiln is at work, burning 100 barrels daily. More kilns will be put in soon. F. Nelson is manager of the White Crystal Lime Co., which controls the property.

#### Jackson County.

J. H. Leggett and Co. of Oroville, Cal., are prospecting ground near Willow Springs, 9 miles from Medford, preparatory to putting in a dredger. Other companies are prospecting and holding land in the same district.

#### Josephine County.

In the Sucker Creek district the Gold Pick claim, located last year by F. Fowler, has been purchased by Matthews & Hull for \$6000. The ledge outcrops on a steep hillside and into this two tunnels have been driven, tapping the vein to a depth of 120 feet.—The Briggs claims in the same district, sold last year for \$110,000, are being developed by the Gold Bar M. Co. of Chicago.—The Sucker Creek district is on the boundary between California and Oregon and is reached by a wagon road 40 miles from Grants Pass to Holland and from Holland 20 miles by trail.—A. H. Mead of Grants Pass and C. C. Case of Cottage Grove are said to be opening up good ore in the Black Oak mine in the Jones Creek district, 3 miles east of Grants Pass.

### SOUTH DAKOTA.

#### Lawrence County.

The Clover Leaf M. Co., working the Uncle Sam mine, at Roubaix, expect to have their 60-stamp mill crushing

rock during June. They intend sinking to the 1000-foot level and also enlarging the mill.

The 120-stamp mill and cyanide plant of Horseshoe M. Co., at Terry, has been burned. It was the largest wet crushing cyanide mill in the Black Hills.

J. B. Taylor of Rochford, S. D., superintendent of the Black Hills C. Co. and of the Burlington G. M. Co., will resume operations on both of these properties during the coming month.

The annual report of the Spearfish G. M. & R. Co. at Cyanide, for the year ending May 1, 1905, shows that 2133 feet of drifts have been run on the second or lower ore zone at the Black Diamond workings on development account. Since January 1, 1905, the larger part of the mill tonnage has been taken from ore bodies opened up by this work and lying about the whim shaft. Attention is called to the rise in the mill tailings since January. From May 1 to January 1, the mill tails averaged 53.5 cents, while from January 1 to May 1, of this year, the average has risen to \$1.14, due to a change in the character of the ore, it being very much denser than the ore from the upper contact. It has been found by mill tests that by crushing this ore to six mesh, instead of three mesh, as formerly, an additional saving of 40 cents can be made. Therefore, the management has ordered the one additional set of rolls, elevator and screens needed for this finer crushing. D. N. Heizer was elected president; W. C. Frost, vice president; C. E. Heizer, secretary and treasurer.

At the annual election of officers of the Big Four G. M. Co. at Deadwood, G. L. Allen was elected president; A. N. Beal, treasurer; B. G. Franklin, secretary, Hamburg, Ia.—The Gladiator G. M. Co. intends to start work again on its property in Deadwood gulch, northeast of Lead.

#### Pennington County.

Satisfactory results are reported from the Redfern mine, near Redfern. The company expects to build a mill on the property this summer.

### UTAH.

#### Juab County.

Work has been resumed on the Lilly property, near Eureka. The shaft is down 275 feet.—Near the Lilly mine, the Big Hill claims are being worked by J. Bestmeyer.—Satisfactory arrangements having been made with the smelters, work at the Swansea mine, at Silver City, will be resumed.

Superintendent S. McIntyre has 112 men at work for the Mammoth M. Co. at Eureka.—Superintendent A. Boudry is opening up good ore on the 400-foot level of the Joe Bowers M. Co. at Eureka.

#### Salt Lake County.

The Continental-Alta at Alta has its bucket tram running.—The Columbus Consolidated mill is running steadily.—The Albion, the Quincy, the South Columbus, the Silver King, the Bryan and the Granite at Alta are all being worked.

The management of the Bingham and New Haven, at Bingham, has decided to build a 4600-foot tramway to make direct connection with the Copper Belt Railway line. At present the company is turning out an average of eighty tons of ore daily.

President E. L. White of the Bingham Con., at Bingham, says that on the Lark vein, in the Mascot tunnel, they are driving east and west and have exposed ore on the 1400-foot level. The copper values have run from 4% to 17%; silver, ten ounces; lead, 20%.—The Miner's Dream property has been drained and they will begin driving from the Mascot tunnel under the Miner's Dream. The tunnel will tap the property 600 feet lower than the lowest workings.—All the ore from the Dalton & Lark properties will hereafter be handled through the tunnel, which, in comparison with hoisting costs, will mean a saving in expense.—In the Eagle & Blue Bell they are down 950 feet and the shaft will be sunk 50 feet more.

Superintendent L. R. J. Morser of the Intermountain M. & I. Association, operating the Mystic Shrine in Bingham canyon, has recommended that the company put up a small concentrating plant to handle the second-class ore. F. G. Shaffer of Denver is manager.—S. Rogers is putting in concentrating machines near the Lead mill to handle tailings in the lower part of Bingham canyon.

#### Tooele County.

In the Erickson mining district recent discoveries of ore bodies carrying high values in copper have attracted attention. The Flying Dutchman, owned by H. Housh, T. Manion, and other parties of Grand Junction, Colo., is following the hanging wall down an incline for 100 feet. T. Manion, the manager, has been directed to crosscut the vein.

#### Utah County.

A circular address by the American directors of the Boston Con. M. Co. to its shareholders advises them of the action which has been taken that a provision may be made for the erection of a concentrator upon the margins of Utah lake. It is proposed to build a railroad from the mines to the millsite which has already been purchased by the company at Pelican Point, on Utah lake, together with equipping the mines with steam shovels for extracting from 5000 tons to 10,000 tons daily. President S. Newhouse advises that a mill of 2500 tons capacity be first erected, and, when completed, add another unit of 2500 tons to the mill, so as to give a capacity of 5000 tons per day. To show that a profit of \$1.25 per ton upon the copper-bearing porphyries can be obtained, he states that 1.4% copper equals 28 pounds copper; deduct 25% loss in concentration, 7 pounds copper, leaves 21 pounds copper; 21 pounds copper at 13½ cents is \$2.83; add gold and silver values, 20 cents, and there is \$3.03. Deduct—Mining cost with steam shovel, 40 cents; milling cost, 35 cents; smelting cost, 25 cents; 2 cents per pound copper for freight and refining—42 cents; for loss in smelting and expenses selling copper, 16 cents; hauling crude ore, 20 cents; total, \$1.78; \$1.78 deducted from \$3.03 leaves \$1.25. W. C. Thomas is superintendent of the site on the margin of Utah lake, upon which is to be built the town of Bostonia.

T. Symms has leased the Hilda mine in Beef Hollow, near Lehi.—W. F. Butt and J. N. Butt, who own a

mine near Simpson Springs, near Lehi, are preparing to ship ore.

J. A. Kauffman, superintendent of the Bingham Metals Co., claims to have copper porphyry on the Mt. Aetna group, 3 miles from Bingham. This is to be developed by a tunnel from Middle canyon.

The Buckley mine, in Rock canyon, east of American Fork, is under the management of Woodward Bros. of Provo, who are working two shifts, finishing the shaft, which will connect with the upper tunnel, from which they are extracting ore. The shaft will be used to supply air and facilitate the handling of the ore in the upper tunnel.—T. M. Alman of Provo is general manager of the Melha M. Co. of American Fork canyon.

—J. Armstrong and J. Burgess are working on the Clipper and Silver King property, in American Fork canyon.—Manager G. Tyng of the Wyoming mine, in American Fork canyon, expects to ship 800 sacks of ore in July.—A. Dickerson and W. H. King are at Mill Fork, of the American Fork canyon, near the Wyoming mine, building a road preparatory to putting in a saw mill to saw mining timber for the Wyoming mine. Geo. Pulley has started work at the Copper King mine, in American Fork canyon.

### WASHINGTON.

#### Ferry County.

The Oversight M. & M. Co., with ten claims 10 miles northeast of Republic, is exploring to find a place for a working shaft through which the vein may be developed.

The Belcher Mountain Railway Co., organized by the interests which are hacking the Belcher mine, at Belcher, near Republic, has an engineering corps in the field making the final location. T. M. Hammond, Jr., has charge of the engineering end. J. L. Harper, general manager, says that the road has been fully financed and negotiations are in progress for the steel and rolling stock. Mr. Harper, who is also manager of the Belcher mine, will buy 2000 feet of steel pipe line, a water wheel, a heavy electric generator and complete electrical equipment for the mine, capable of running eight drills. A gravity tramway 2000 feet in length will transport the ore and flux from near the top of Belcher mountain to the railroad bunkers at its base.

### WYOMING.

#### Fremont County.

The property of the Basin Copper M. Co. on Copper mountain, near Thermopolis, has been sold to P. Reisgaart of Alma, Colo., for \$150,000.

### FOREIGN.

#### AUSTRALIA.

##### New South Wales

Opal is found in Wallangulla in an outlier of the upper Cretaceous (sandstone), which comprises an upper bed of conglomerate 30 feet thick, which has in places been denuded, resulting in the formation of a low ridge and a lower bed of white, powdery siliceous rock. The conglomerate is composed of a number of quartz pebbles set in a vitreous ground mass. The lower bed contains the precious stones and is similar to the opal-bearing rocks at White Cliffs. The precious stone is scattered in an irregular manner through the rock and frequently occurs in a nodular form. The field has yet to be developed.

### CANADA.

#### BRITISH COLUMBIA.

The annual report of the British Columbia Minister of Mines for 1904 shows the following production of mineral by districts and divisions:

Name.	Divisions	Districts.
Cariboo District.....		\$474,600
Cariboo Mining Division.....	\$218,000	
Quesnel Mining Division.....	150,000	
Omineca Mining Division.....	11,600	
Cassiar District.....		\$558,573
East Kootenay District.....		\$3,210,573
West Kootenay District.....		\$5,806,070
Albermarle Division.....	\$168,023	
Nelson Division.....	466,633	
Slocan Division.....	1,236,558	
Trail Creek Division.....	3,760,866	
Other parts.....	173,640	
Lillooet District.....		\$34,583
Yale District.....		\$4,190,281
Osoyoos, Grand Forks & Greenwood Divis's.....	\$4,110,366	
Similkameen Division.....	2,500	
Yale Division.....	7,415	
Coast Districts (Nanaimo, Alberni, West Coast Vancouver Island, Victoria).....		\$4,702,679
Total.....		\$18,977,359

The amount and value of mineral products was:

	Weight.	Value.
Gold, placer, ounces.....	55,765	\$1,115,300
Gold, lode, ounces.....	2,2,042	4,589,608
Silver, ounces.....	3,222,481	1,719,516
Copper, pounds.....	35,710,128	4,578,087
Lead, pounds.....	36,616,244	1,421,874
Coal, tons.....	1,253,628	3,760,884
Coke, tons.....	334,102	1,192,140
Other material.....		600,000
Total.....		\$18,977,359

#### Boundary District.

Although mine and claim owners in the west fork of the Kettle river country have no railway nearer than the Canadian Pacific Railway terminus at Midway, yet developing the mineral properties is being actively undertaken. The Vancouver & Boundary Creek D. & M. Co., operating the Sally group, has completed a wagon road from Beaverdell, on the east side of the west fork. North of the town is Wallace mountain, on which most of the company's claims are located. The Sally group has ten veins, with a northeast and southwest direction, and a dip to the east. On vein No. 1, on the Sally, a tunnel has been driven 300 feet, with an 80-foot upraise at 100 feet. The ore contains a little gold and some gray copper, with most of the value in silver. Other properties being developed in the same district are the Wellington, on Wallace mountain, the Bounty, the Gold Drop Fraction, the Nanapsee, 2 miles from Wallace mountain, and the Curry group, on Curry creek

Experiments are being made to amalgamate and concentrate the values at the Carmi mine, where a small mill has been put up.

J. P. Graves, manager of the Granby Co., states that a new shaft, to cost \$100,000, will be constructed at once on the Victoria of the Granby group of copper-gold mines at Phoenix. It will have three compartments and will be excavated by raising above the 400-foot level to the surface. It will be equipped with a crusher capable of handling 1500 tons in ten hours. It will be the principal working shaft and through it about one-third of the mine output will be raised. That will put the mine in shape to produce from 4000 to 5000 tons a day. The seventh and eighth furnaces at the smelter, giving it a capacity of 2700 tons a day, will be running July 1. A ninth furnace may be put in this year.

L. T. Dickason, E. F. Johnson and W. Bailey of Chicago, Ill., have purchased the Preston mine, adjoining the Crescent mine, near Greenwood. Work has begun under W. H. Jeffery.

The new 80 H. P. boiler for the Providence mine near Greenwood has been put in place and development resumed.—The new incline shaft on the Emma, Summit camp, is down 130 feet, and is to be continued to 160 feet. Shipments have been resumed.—M. Kay will resume development on the Toronto, near the Skylark.—The Jewel mine in Long Lake is being unwatered. It is probable that as soon as the water is taken out of the mine, the drift will be continued into the Denoro Grande, recently bonded by the company from C. J. McArthur.

Ore shipments from Boundary mines for the week ending May 27 were as follows: Granby mines to Granby smelter, 12,080 tons; Mother Lode to British Columbia Copper Co.'s smelter, 3808 tons; Mountain Rose to British Columbia Copper Co.'s smelter, 33; Emma to Nelson smelter, 99; Oro Denoro to Granby smelter, 66; Skylark to Nelson and Granby smelters, 50 tons; Last Chance to Trail smelter, 30 tons; total for week, 14,166 tons; total for year to date, 378,204 tons. The Boundary smelters treated ore as follows: Granby smelter, 12,413 tons; British Columbia Copper Co.'s smelter, 4147 tons; total for week, 16,560 tons; total for year, 387,069 tons.

#### Cassiar District.

Regarding work in the Atlin district, the British Columbia Mining Exchange says that while the sluicing season started in early on the principal creeks, there were no signs of Atlin lake breaking up on May 10.—The dredger on Upper Spruce creek is to be completed this year. The same investors will build an electrically equipped dredger to operate on Tar Flats.—Ruffner's consolidated companies on Pine creek will operate with 7000 inches of water after the ditch is enlarged. McKee Creek Con. will also extend and enlarge its operations.—Spruce Creek Power Co. will be operated this year by W. H. Hall for the Denny-Blaine people of Seattle.—Otter creek will be operated this year under lease by J. M. Britt of Grants Pass, Or., and T. B. Raefield of Seattle, Wash. The management of the company will continue in the hands of O. T. Switzer and J. H. Brownlee.—The steam shovel for the Northern Mines, Ltd., will go into Atlin by the first boat. Meanwhile contracts have been let for getting out the necessary timbers. This company has acquired 2600 feet of the richest and best prospect portion of Spruce creek. A. H. Bromley and R. D. Fetherstonehaugh are interested in the company.

#### Roseland District

The tonnage of ore shipped from and crushed at the Roseland mines for the week ending May 27th and for the year to date was as follows:

Le Roi	1,875	53,355
Centre Star	1,820	37,920
War Eagle	1,320	26,850
Le Roi Two	80	3,953
Le Roi Two (milled)		2,800
White Bear	1,100	9,830
White Bear (milled)		3,725
Jumbo	100	3,894
Spitzee	30	1,977
Velvet-Portland		
Total	5,305	139,504

#### Slocan District.

Manager McPhee of the Ottawa mine, a dry property on Springer creek, near Slocan City, states that the owners intend to develop the mine by putting in a small compressor for the necessary power. The throwing open of the railway reservation lands by the Government on May 24 caused a big rush of locators, who have staked locations for timber, water and land near Kaslo, Slocan and on the banks of the Columbia above Trail.

### CHINA.

The United States Consul-General at Tientsin submits what is believed to be a complete schedule of mining concessions granted by the Chinese Government: In the three eastern provinces, to Russia, Karin, Chiapiku, Ningkuta and Hunchun. In Shantung, to Germany, all places along the Kiaochau Railway and almost the whole province; capital, \$60,000,000 Mexican. In Szechuan, to France, Kuanhsien, Kienwei, Weiyeun, Chikiang, Huchau and Chingking; capital, \$10,000,000 Mexican. In Shansi, to England, Menghsien, Pingting, Luan and Tsechau; capital, \$732,000. In Honan, to England, Huaiching and its neighborhood; capital, \$7,320,000. In Anhui, to Japan, Hsuancheng; capital, \$1,830,000. In Chehkiang, to Italy, Yenchau, Wenchan and Chuechau; capital, \$3,660,000. In Kuichau, to France. In Chihli, to Americans, Lowry & Jameson, gold mining claim.

### HONDURAS.

W. E. Alger, consul, Tegucigalpa, reports a rich discovery of copper in the department of Yoro. The discoverers have located eight well-defined veins; which can be traced for miles on the surface, two of these being 12 feet wide. The consul states that the properties are surrounded by forests of oak and pine, a coal deposit is within 20 miles, there is abundant water power sufficient for any machinery needed for reduction, etc., and that it is comparatively close to transportation—40 miles from the Ulua river, which is connected by canals with the bay at Puerto Cortes.

### MEXICO.

A decree has been issued by President Diaz to the effect that one or more parties may hold several mining claims by one title, for which they will pay only \$6 per portencia for the first twenty-five, and \$3 for every one thereafter; this is to be the case whether the claims are adjoining or otherwise. Also the decree covers persons holding claims under different titles, but adjoining, who may petition the government for the same charges.

#### Chihuahua.

Governor Creel has granted a concession for a reduction to J. F. Johnston of Parral, who says that his smelter will be of 500 tons capacity. The concession gives Mr. Johnston six months from the first official publication of the concession in which to begin work and eighteen months from the same date to complete it. The minimum capacity of the plant allowed is 200 tons daily and the minimum amount he can expend upon it is \$100,000. Mr. Johnston is allowed to select his smelter site in Jimenez, Parral or Allende. The concession carries with it the right to condemn lands for the site of the plant, the right to build dams for impounding water, etc., general exemption from all State and municipal taxes for fifteen years.

#### Durango.

The Guauacevi Exploration Co. has purchased the Rafael mining properties near Guanacevi, and will operate them.

To treat the ores of the Abra mine in the San Dimas district, the Haggin-Hearst interests, it is stated, will put in a 40-stamp reduction mill.

#### Guerrero.

The Trinidad mine, near Raton, in the Aldana district, after frequent experiments, has adopted a process which will successfully treat the ores which have been developed. B. Davidson is general manager.

#### Jalisco.

F. Valderrama has sold the Abaradon mine, in the Hostotipaquillo district, to Carlos Romero of Guadalajara for \$20,000. As soon as there are 50,000 tons of milling ore on the dump reduction works will be commenced.

H. M. Sunde is getting high-grade ore out of the San Jose de las Agujas mine on the Agujas mountain in the Navidad camp. A double-compartment shaft is down 135 feet, and there are 250 feet of drifts.—U. Johnson of Los Angeles, who has been prospecting for oil east of Zapotlan, is said to have struck a deposit of coal.

The San Antonio y Anexas mines in the municipality of Tapalpa have been sold to the Chatterton M. Co., who intend to spend \$100,000 in the purchase of machinery for the mines and in the erection of the reduction works. N. W. Kinross is manager.

#### Puebla.

The Cia. Minera de Mexico has started its 150-ton chlorination and cyanide plant at Tetales, under the direction of H. Cabrero, who states that the company has 80,000 tons of manganese ore, carrying gold, in sight, and that work of development is going on. R. H. Hutson is general manager and L. Chevrillon is chief engineer.

#### Sinaloa.

The bismuth mine in the Rosario district, owned by G. Petersen, has been purchased, it is reported, by O. L. Jones of Oklahoma City, Ok.

#### Sonora.

The Sonora Coal & Land Co. has been incorporated to acquire coal lands in the State of Sonora.

Superintendent E. W. Jones will start the Cerro Azul M. Co.'s gold mines, 15 miles east of Imuris.

In the Caliche region, on the Santo Domingo river, 3 miles from Cerro Prieto, Las Tres Naciones G. M. Co. have fifty men at work, and have sunk two shafts each 100 feet, and going yet deeper, with a tunnel 150 feet in length. The Calera mill has been leased and repaired to treat the ore. A. B. Oliver, consulting engineer for the company, will start work on a new 20-stamp mill, which will be built on the Santo Domingo river and connected with the mine by an aerial tramway. A. W. Morris is superintendent and F. J. Johnson is mill foreman.—T. M. Clancy at Cananea has put in a hoisting engine, a boiler and an air compressor.—H. C. Reno, manager for the Trinity M. Co., has taken over the Jojoha mine at Magdalena.

#### Zacatecas.

Statistics on the mineral production of the State of Zacatecas during 1904 show that the total value of the mineral produced in the twelve months was \$6,684,463.07. Of this amount the ore shipped out of the State for treatment elsewhere represented a value of \$5,409,406.27 and that treated in the State had a value of \$1,275,056.80. Only gold and silver were treated in the State, all copper and lead produced being sent out of Zacatecas for treatment. The values of the different minerals were as follows: Silver, \$5,709,858.76; gold, \$581,281.87; copper, \$269,421.36; lead, \$123,901.08.—At the Mezquital gold mines at Mezquital del Oro remodeling the 50-stamp mill has been completed and a new steam hoist is being put in. The cyaniding plant at the mines is to be enlarged. M. Cockerell is manager.

### Trade Treatises.

The Hydro-Carbon Mfg. Co. of Denver, Colo., describe the uses of "Elatecote Coatings" for preserving metal and wood from heat, acid and atmospheric agencies in a neat booklet which includes copies of a number of letters received from users.

The Quincy Corliss and vertical engines are described in Bulletins 104 and 103, respectively, issued by the Quincy Engine Works, Quincy, Ill., represented on the Pacific coast by the California Hydraulic Engineering & Supply Co., 17-19 Fremont street, San Francisco, Cal.

"Far Down Beneath the Upper World" is the title of an unusually fine folder from the Watt Mining Car

Wheel Co., Barnesville, Ohio. It is for mine operators and artistically portrays the workings of a number of large mines in different parts of the Union. Each mine so noticed has a page to itself and the idea is finely worked out. There are a few figures of coal production, a graceful word of preface, and the rest is all pictures, the whole constituting a fine advertisement of the Watt Mining Car Wheel Co.

### Personal.

C. D. LANE has gone from San Francisco, Cal., to Nome, Alaska.

E. L. DOBBE has returned to Salt Lake City, Utah, from a California visit.

C. E. FINNEY has charge of construction of the smelter at Val Verde, Ariz.

N. C. BONNEVILLE, Denver, Colo., has returned there from Salt Lake City, Utah.

C. A. BEATTY is examining the Utah Copper Co.'s holdings at Bingham, Utah.

F. E. MARCY with Allis-Chalmers Co., Chicago, Ill., was in Denver, Colo., last week.

N. C. BANKS, Magdalena, Sonora, Mexico, is manager Black Mountain G. M. Co.

JAS. RULE of Nevadaville, Colo., has been appointed manager Roderick Dhu G. M. Co.

S. GOOD has been appointed manager La Luz M. Co. at Cusburiachie, Sonora, Mexico.

H. J. B. BAIRD has been appointed manager Goldfield Great Bend mine at Goldfield, Nev.

T. H. TRACY, of the Power & Mining Machinery Co. of New York, is visiting California.

J. L. GRIMES is superintendent of the Black Canyon mine at Westville, Placer county, Cal.

ALEX. ROSSI has charge of the Graham mines in the Copper City region, near Redding, Cal.

W. JAMES of London, Eng., has been in San Francisco and examining mines in California.

N. E. HECKELTHORN has returned to Warren, Idaho, from Florida and will develop his mines.

WM. C. EAKINS has returned to Arlington, N. J., from San Francisco, Cal., via Goldfield, Nev.

L. W. TRUMBULL has accepted a position as consulting engineer Strong Copper M. Co. at Leslie, Wyo.

A. M. PLUM has returned from Alabama to Lewistown, Mont., where he is looking after his mining interests.

J. A. INGALLS has been appointed superintendent of the Majestic copper mine at Milford, Beaver county, Utah.

GEORGE OSWELL has been appointed superintendent Highland mine, near Sumpter, Or., vice O. Herlocker, resigned.

CHARLES KAMMERER has been appointed superintendent of the dredgers of the Conrey M. Co. at Ruby, Montana.

H. F. POOL has charge of work at the West Notaway mine in the Russell district, near Central City, Gilpin county, Colo.

L. W. BONNEY, who has been operating mines in the Magdalena district, Sonora, Mexico, will be in Seattle, Wash., until fall.

W. SKEWES has resigned as manager Challenge property of the St. Mary's Mineral, Land & Canal Co. at Houghton, Mich.

C. C. CHAPPELL, manager Denver office Westinghouse Machine Co., has returned to Denver, Colo., from Salt Lake City, Utah.

H. W. MORSE, for three years past the assistant manager of the Morning mine, at Mullan, Idaho, has been appointed general manager.

F. M. CLARK has resigned as assistant superintendent South Eureka mine, Sutter-Creek, Cal., to go to a mining property at Bullfrog, Nev.

C. W. PHILIPS is manager Las Tres Naciones G. M. Co. working on the Santa Domingo river, 3 miles from Cerro Prieto, Sonora, Mexico.

H. VINCENT WALLACE has severed his connection with Vela Grande Co., Altar, Mexico, and is now with Roy & Titcomb, Nogales, Ariz.

J. M. MCSHANE, representing the Broderick & Bascom Rope Co., has returned to St. Louis, Mo., from a general tour of the Pacific coast.

S. BOWERS of Los Angeles, Cal., has been examining the saline deposits of Danby lake, 25 miles southeast of Danby, San Bernardino county, Cal.

R. MCF. DOBLE, consulting engineer of the Abner Doble Co., San Francisco, Cal., is in Mexico investigating hydro-electric long-distance power projects.

R. B. LAMB has resigned the management of the Great Tower Hill gold mines, Lenora, West Australia, to return to the United States on mining business.

B. W. VALLAT has resigned as mining engineer for the Bay State Iron Co. at Virginia, Minn., to become engineer for the Colorado Fuel & Iron Co. at Sunrise, Wyo.

GEORGE ALEXANDER has been appointed manager of the Ferguson mines, Ltd., at Ferguson, near Five Mile, Trout Lake mining district, which controls the Nettle L., Silver Cup and other mines.

## Books Received.

The United States Geological Survey has issued the "Silverton Folio," No. 120, giving descriptive text, topographic map, areal geology map, economic geology map, structure section sheet, columnar section sheet and illustration sheet of Silverton, Colo.

"Annual Report of the Minister of Mines" for the year ending Dec. 31, 1904, gives an account of mining operations for gold, coal, etc., in the province of British Columbia. In addition to the usual information regarding mining operations, the volume contains drawings graphically illustrating the metallurgical processes at different plants, tracing from the raw material to the finished product.

The complex methods of gas analysis are collected and simplified and their application explained in "The Investigation of Mine Air," by C. L. N. Foster and J. S. Hal-dane. The book gives an account by several authors of the nature, significance and practical methods of measurement of the impurities in the air of coal and metal mines. The first part is a translation of O. Brunck's "Simple Methods of Mine Air Analysis." The second part is a description of methods used in the measurement of air currents and fire damp at the Ronchamp collieries, by L. Poussigue. The third part contains an account of rapid methods of air analysis, by J. S. Hal-dane. The appendix graphically describes the effects of carbonic acid, by C. L. N. Foster. The methods presented are comparatively simple and may be performed rapidly. The life of the miner depends upon the care taken in ventilation, and whatever advances knowledge on this subject should be studied by the mining engineer. The methods described are mainly with reference to gases escaping from the ground and not the result of blasting or respiration which seem to be subsidiary in coal mining. It is published by J. B. Lippincott Co., Philadelphia, Pa.

Experience is man's best teacher, but young engineers are often called upon to superintend work about which they know but little. To such, "Earth and Rock Excavation," by Charles Prelini, will contain much valuable information. The planning and execution of work involving excavation and the means employed in such work are the author's subjects. He begins with a discussion of the graphical representation and calculation of earth work, describing the methods of marked points, of contour lines and of profile and cross sections. This part of the subject is often overlooked by American engineers, and in his endeavor to impress its importance the author devotes considerable space to theoretical and mathematical discussion. Then follow chapters describing the construction and operation of machines used in excavating and transporting earth and rock, including various blasting agents. This section of the book seems somewhat verbose and is far from being complete, yet many of the various types of cutting and conveying machinery are illustrated and can be supplemented by catalogues of different machinery houses. The succeeding chapters on methods of planning and executing works of excavation constitute the most valuable part of the book. The author hits the keynote of successful work when he lays emphasis on the importance of the handling and care of the men doing the work. The practical man will be amused by the usual theoretical statements of foot pounds of work performed by ideal men working continually, but will profit by some really practical hints on pushing work. The book is concluded by statistical description of large works of excavation. The chief fault to be found in the book is the lack of detail as to costs. Engineers are everywhere looking for statements of costs under all conditions and a record of these often forms the most valuable part of their experience. The book makes no attempt to deal with underground problems, and will be of value mainly to railway contractors, ditch excavators and building constructors, although some space is also devoted to quarrying. In reviewing, undue prominence may have been given to a discussion of the shortcomings, for the book is an excellent step in the direction of systematizing engineering data. It is published by D. Van Nostrand Co., 23 Murray street, New York, for \$3, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Commercial Paragraphs.

THE Miners' Assay Office, John Harrigan proprietor, has been moved from No. 19 to 25 Stevenson street, San Francisco, Cal.

THE Wagner Electric Mfg. Co. has opened an office at 417 Rialto Bldg., San Francisco, Cal., with A. J. Myers in charge as district manager.

THE Vulcan Iron Works Co. of Toledo, Ohio, have shipped one of their Little Giant steam shovels to the Northern Mines Co., Ltd., of Atlin, B. C., for placer work.

THE San Francisco office of the Allis-Chalmers Co. is moved from the Kohl Bldg. to the ground floor, Rialto Bldg., Cor. Mission and New Montgomery streets, San Francisco.

THE Power & Mining Machinery Co. of Cudahy, Wis., and 52 William street, New York, has established a branch office at 215 Commercial Club Bldg., Salt Lake City, Utah, with Geo. F. Waddell as district manager.

T. L. KNUDSON, who has been in the mining machinery business for twenty-five years, has formed a company under the name of Knudson-MacDonald Co., with offices at 414 Stock Exchange Building, Chicago. They will handle a general line of mining and cement machinery, including crushing, grinding, pulverizing

and air separating machines, and will also act as consulting engineers.

THE S. H. Supply Co., of Denver, are furnishing three complete air compressing plants with American compressors, for which they are Western agents, one going to the Ohio-Mexican M. Co. in Arizona and two to Colorado. This company is also furnishing a No. 2 Wild mill to Idaho and two Wild shaking screens to Old Mexico.

COLORADO IRON WORKS COMPANY of Denver, Colo., report the following shipments: To the Great Western Sugar Co., at Fort Collins, Colorado, two 11x15-inch Dodge crushers and one set of 20x12-inch Compromise rolls; to the same company at Loveland, Colorado, two 11x15-inch Dodge crushers, one set of 20x12-inch Compromise rolls and three carloads of steel tanks and fittings; to the Denver City Tramway Co., one impact screen, one 11x15-inch Dodge crusher and one 60-foot belt elevator and equipment; one impact screen to the School of Mines, Kingston, Ontario, Canada; one set of 27x14-inch improved standard crushing rolls to the Mazapil Copper Co., in Mexico; two impact screens to the H. & B. Mining Co. in Colorado; five carloads of sheet steel dust flues, etc., for the Bingham smelter at Bingham, Utah; two sets of 27x14-inch H. rolls to the Success Mining Co. in Montana; one 32-foot Oxland roaster, dryer and equipment for the Julian Mining Co. in California; concentrating equipments for the El Cobre Copper Co. in Cuba; four all-iron Perfect pattern ore feeders for the Lone Star Mining Co. in Nicaragua, C. A.

## Obituary.

J. S. ICKIS, one of the owners of the Barranca del Oro mine in Tepic, died at Guadalajara, aged 38.

D. W. GILLISON, engineer for the Tonopah Water Co., was killed by being caught in the pumping machinery at Rye Patch, Nev., on May 31.

FRANCIS HEURTEVANT, a mine owner of Trinity county, was shot and killed May 25 on the banks of Trinity river, 4 miles below Junction City, Cal., by an unknown man. He owned the Red Hill mine.

JAMES CROSS, a California mine operator and manager, who for years has been identified with the Hayward and Hohart interests in Nevada and California, died at his home in Stockton, Cal., May 31, aged 65 years.

## Latest Market Reports.

SAN FRANCISCO, May 31, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, \$15.00; Lake, 1 to 3 casks, \$15.00@15.00; Electrolytic, 1 to 3 casks, \$15.00; Casting, 1 to 3 casks, \$14.75@14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £65 3s 9d spot per ton.

During the week there has been no material change in the copper market either at home or abroad. Prices are about the same, with no unusual features to distinguish the market. There has been a slight falling off in price the past month—the fraction of a cent—but for the present, unless something unforeseen occurs, the price is not likely to advance. The temporary closing down of the United Verde mine at Jerome, Ariz., will possibly effect the supply on hand eventually, but this will probably not be noticed within sixty days, if at all. There are always these irregularities in the market. Producing mines are closed temporarily, new mines are opened and other changes are constantly taking place, but the output shows about the same tendency throughout, with a steadily increasing production to meet the increasing demand.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots, 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 17s 6d per long ton.

SPELTER.—New York, \$5.50; St. Louis, \$5.70; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.85@30.20; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 35@37½c. London, £136 5s.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c. SOLDIER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, 50c; dust, 40c; 10c; sulphate, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c. ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.25@16.25; gray forge, \$16.00; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer hillets, Pittsburgh, \$23.00@25.00; open hearth hillets, \$23.00@25.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c;

in 25-lb. tin pails, 1c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In hbls., 1 ton and over, 6½c; do. in kegs, 7c. LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl. CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brynmor, \$7.50; Pennsylvania, h.d., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. O. B. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chloride of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linsed, boiled, hbl., 62c; cs., 67c; raw, hbl., 60c; cs., 65c; Lucol oil, boiled, hbl., 54c; cs., 59c; raw, hbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 18c; As; tral, 18c; Star, 18c; Extra Star, 21c; Ecocene, 20c; Elaine, 26c; Water White, in bulk, 11½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 53@68c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, 7½c per lb., 80c.

PHOSPHORUS.—American, 70c per lb., 70c.

SODIUM.—Metal, 50c per lb., 50c.

BISMUTH.—Subnitrate, 7½c per lb., \$2.10.

SILVER.—Chloride, 7½c per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 7½c per lb.; less than 500 lbs., 7c.

MANGANESE.—Black oxide, 7½c per lb., 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewhaek, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, 7½c per ton 2000 lbs. in 125-lb. hags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MAY 23, 1905.

790,863.—FURNACE—J. H. Anderson, Los Angeles, Cal.  
790,864.—FURNACE—J. H. Anderson, Los Angeles, Cal.  
790,474.—FOLDING BED—J. C. Bahr, S. F.  
790,422.—OIL BURNER—G. S. Bennett, S. F.  
790,777.—FURNACE—W. N. Best, Los Angeles, Cal.  
790,613.—AMUSEMENT DEVICE—J. C. Boyle, Portland, Or.  
790,345.—LAMP SHADE SUPPORT—F. N. Cooley, S. F.  
790,280.—CAMERA—J. S. Ditty, S. F.  
790,552.—WATER ELEVATOR—V. A. Douglas, Anacortes, Wash.  
790,553.—IRRIGATOR—E. S. Estlin, S. F.  
790,556.—ROTARY ENGINE—A. F. Ford, Colfax, Wash.  
790,823.—BORING MACHINE—J. M. Garfield, Los Angeles, Cal.  
790,825.—FURNACE—C. R. Glafke, Los Angeles, Cal.  
790,832.—WINDOW SHADE—M. L. Hansen, S. F.  
790,684.—TELEPHONE CALL—Harveston & Mudgett, S. F.  
790,734.—OIL BURNER—P. H. W. Harvey, Los Angeles, Cal.  
790,432.—TOOL—C. L. Heilrich, Sacramento, Cal.  
790,337.—FRUIT BAG—F. L. Hepler, Covina, Cal.  
790,634.—FURNACE JOINT—O. H. Hicks, Riverside, Cal.  
790,636.—STUMP BURNER—C. N. Hubbard, Bee, Wash.  
790,630.—WASHING MACHINE—P. P. Kiehl, Oakland, Cal.  
790,580.—PRUNE DIPPER—C. J. Kurtz, Salem, Or.  
790,734.—OIL BURNER—P. H. W. Harvey, Los Angeles, Cal.  
790,532.—LOOSE LEAF BINDER—G. McBride, Golden Gate, Cal.  
790,651.—FLY TRAP—J. McConnell, Raine, Wash.  
790,653.—DOOR SECURER—H. Nottthoff, Santa Monica, Cal.  
790,703.—WINDOW SHADE ADJUSTER—W. C. Organ, Oakland, Cal.  
790,403.—OILING ROADS—I. E. Smith, Sacramento, Cal.  
790,710.—HORSE RELEASER—A. P. Weeks, Santa Cruz, Cal.  
790,775.—STAPLE SETTER—F. Wiseman, John Day, Or.  
790,415.—ANALCAMATOR—O. W. Zane, Los Angeles, Cal.

# MINING AND SCIENTIFIC PRESS

Whole No. 2342.— VOLUME XC.  
Number 23.

SAN FRANCISCO, CAL., SATURDAY, JUNE 10, 1905.

THREE DOLLARS PER ANNUM.  
Single Copies, Ten Cents.

## Great Mills in Alaska.

In the earlier history of mining on Douglas Island, Alaska, the mill of the Alaska-Treadwell mine was comparatively small, and when the proposition to increase the number of stamps was made, the matter was seriously considered for some time before it was finally determined to take the risk which such investment involved. It was argued by those in

favor of a larger mill, that the greatly increased capacity would result in lowering the cost of milling, as it had already been determined that there was abundance of ore available, and it was finally determined to enlarge the mill to 240 stamps. The venture at once proved a success, and the profit per ton of ore crushed was increased. Since then the number of stamps has been increased several times. Profiting by the past experience of the Alaska-

Treadwell Co., the Alaska Perseverance Co., operating near Juneau, will begin the construction of a 300-stamp mill. The great ore deposits of Douglas Island have been shown to be well adapted to the great mills built on them, but these mills are thus far the result of the gradual development of the mines, and the proof of the ability of the mines to keep the stamps constantly supplied with a payable grade of ore.

## The Copper Situation.

The consumption of copper has been increasing from year to year during the past decade, there being but a single year when the consumption of the metal did not exceed that of the previous year. This was during 1901. The amount of copper required in the industries in 1893 was 268,447 tons. In 1903, ten years later, it was nearly double this amount, having been 520,944 tons. In 1904 the consumption was further increased to 557,805 tons, nearly 36,000 tons more than in 1903. If the past decade can be considered as a criterion for the future, it seems unlikely that the copper production of the world will be more than temporarily increased beyond the demand. It should be remembered that those mines which are most easily accessible and which afford the greatest immediate profit are being worked vigorously, and are gradually being exhausted—and can never reproduce the metal now being taken out. New discoveries, the reopening of old mines and the enlarging of existing plants are the sources of increase in copper production, but these new mines barely compensate for the rapid exhaustion of the greater properties. Copper occurs in a great many States of the Union, and nearly every country has more or less copper, but it is always a question of economics—will it pay? In most cases the career of an unprofitable mine is short, and it waits until conditions change to an extent that makes profitable operation possible. Usually the transportation problem is the most serious consideration. Then, some mines can be profitably worked with copper at 15 cents or over, which can make nothing at 12 cents or less. Such mines are active or idle, according to the market, and there are many such. At present the copper industry is in prosperous condition, and there is no reason

to anticipate either lower prices or a less demand for the metal. If the present indications—that standard steam railroads are to be equipped with electricity—becomes a fact, the demand for copper will be greatly stimulated, possibly to such an extent as to materially influence the extensive use of aluminum as a conductor.

## Rock Nomenclature.

Elsewhere herein will be found an abstract of the revised ideas of J. E. Spurr of the United States Geological Survey as to the geology of Tonopah district, Nevada. So much interest centers around these new camps of southern Nevada that this latest contribution on the structural and economic geology of so important a district will be gladly received, whether the reader agrees with Mr. Spurr or not. That eminent geologist has the courage of his convictions, at least, and does not hesitate to "coin" a name to suit conditions as he sees them, if no name has already been provided. His "alaskite" is evidence of this tendency. In Alaska Mr. Spurr found numerous aplite dikes which had become silicified, or it may be that the unusually abundant silica in these granitic dikes was original in the magma. To these dikes he gave the name "alaskite," and the name seems to stick. In his geology of Tonopah he has added a new rock to the long list of names in rock nomenclature in "rhyolite-dacite." All students of petrography are familiar with rhyolite and understand what is meant, and all are equally acquainted with dacite (quartz-andesite) and appreciate its significance, but rhyolite-dacite is a refinement of rock classification not recognized by Rosenbusch, Zirkel, Williams, Kemp or any other authority with which we are familiar. Mr. Spurr does not explain in his contribution what is meant by rhyolite-dacite. It may mean a rhyolite in which there is sufficient andesine to incline it toward the andesites, or it may be a typical quartz-andesite (dacite) in which the occurrence of abundant sanidine and a fluidal structure would suggest rhyolite. All petrographers know that the lines of demarkation between rocks are not sharply drawn, but it seems unnecessary to create new names where none are required. It does not appear as essential to the value of the mines that any particular kind of rock be present, yet it is very important that the miners be informed as to the relative age of the various rocks of the district, and in which their veins are situated, for undoubtedly there is more significance in structural conditions than in the character of the rock. Complications should be avoided, as far as possible. Andesite and rhyolite are plain and conventional terms the meaning of which is appreciated, and the prefix "earlier," or "later," will be given due consideration, being self-explanatory, but rhyolite-dacite is perplexing and no one knows what is intended.

## Head Frame Design.

Economy in the construction of head frames is always an interesting and important matter with mining engineers. For many years the practice of building massive four-post frames, with their heavy and expensive back braces and interior angle bracing, has been common. There has been nothing in particular to recommend such structures, aside from the fact that it has been the customary form of pit-head design for many years. These structures are solid, heavy and undoubtedly safe—the factor for safety often being ten to twenty times greater than the most conservative engineer would require. As a result these frames are unnecessarily expensive. Some years ago a different type of frame was introduced—the two-post frame with back braces. This type is often called the Montana frame, from the fact that it was in Montana that it was first extensively employed, though now largely in use throughout the West. The two-post frame is inexpensive, requires far less material than the four-post frame of the same height and is easily constructed, there being few perplexing angles to worry the non-technical mine carpenter. There is, however, a better and more desirable type of head frame construction than either the four-post or the ordinary two-post frame. Elsewhere herein will be found a descriptive, illustrated contribution by a well-known engineer, in which the most advanced type of modern steel head

frame construction is discussed. Here three kinds of frames are shown. The first is the steel frame erected over the shaft of Plant's Day Dawn mine in Charters Towers district, Queensland, Australia. This frame shows the painstaking engineering work that has been put on it, and, if designed to support a large water tank, could scarcely be improved upon. The frame is substantial and makes a handsome appearance, but contains sufficient material to almost build two frames, which would answer every purpose to which the present construction can be applied. On the page opposite to this illustration is the steel frame at the High Ore mine at Butte, Mont. This frame is approaching the advanced modern ideas described and illustrated by the sketches at the bottom of page 374. Without doubt this modern type of frame will, in time, come to be recognized as among the most desirable because tending toward the minimum of expense, and as fulfilling every requirement.

## Deterioration of Hoisting Ropes.

In a recent technical article discussing wire hoisting ropes the writers of the paper attribute the deterioration of winding ropes chiefly to decrease in sectional area, caused by frictional wear of the wires upon each other, or to corrosion; to "fatigue," or a change in the state of the steel from which the rope is made, and to discontinuity of the wires, due to breaking. The frictional wear of a rope is a natural consequence of its use, for no matter how frequently and carefully a winding rope may be greased, there is always a slight movement within the rope when running, particularly as it bends over the sheaves, and upon the drum of the hoist. Any object with which the rope comes in contact must cause abrasion, if ever so slight. The working of the wires upon each other and the wear induced by the winding of the rope upon the drum upon coils of rope already wound are probably the most important causes of wear, particularly the latter. Careful inspection of a rope used in this manner will show this to be so. An examination will usually discover broken wires, and should they become numerous the rope should be abandoned. It is generally recognized that hoisting ropes are subjected to deterioration in a number of ways, but ordinarily nothing in particular is done to prevent it, except to again "oil the rope," after contemplation of the discovery that the rope shows signs of wear.

No rope will last forever, and a rope in constant use should be renewed as often as it shows evidence of material deterioration. The wear on the rope can be reduced by care in alignment, by the installation of sheaves and hoist drums of liberal size to reduce bending strains and consequent wear, and to avoid contact of the rope with a greater number of sheaves and idlers than is absolutely necessary. The hoisting engine should be started and stopped with care, and not with a sudden jerk, as is too often done. It is almost as bad to stop suddenly as to start suddenly when hoisting. There are in many instances too little attention and care given to hoisting ropes, but much can be done in the beginning by putting in a proper installation, in which the relative size of sheaves and winding drums to the diameter of the rope is given the proper consideration, and this is one of the most important matters in the life of a winding rope. Proper alignment is probably the next important factor.

**A**LCHEMY is as old as civilization. In all civilized ages there have been men who made claim to having discovered the secret of the transmutation of silver into gold with as much seriousness and apparent truthfulness as that now assumed by an alleged scientist in Philadelphia, who says he is making extensive preparations to manufacture gold from silver, but he, like his predecessors, will have to give some tangible evidence of his ability to perform this wonderful feat of chemical legerdemain. Those interested in this newest phase of occult science will remember that Philadelphia was for 25 years the home of the Keeley motor, in which its fakir inventor succeeded in interesting some of the leading financiers of his day, but which eventually proved to be merely a trick so simple in its operation as to be laughable, and yet Keeley deceived his backers and held their confidence and money to the day of his death.

## CONCENTRATES.

THE stack of the Tacoma, Wash., smelter is built of concrete and is 307 feet high.

ELATERITE is a wax-like hydro-carbon mined near Fort Duchesne, Utah. It is used in making paint and waterproof material for roofs, walls, etc.

THE manufacturers of diamond drills state that their machines can be successfully operated by means of the gasoline engine, the possibilities depending on the power of the engine.

THE presence of sand in crude petroleum can be at once detected by pouring some of the oil on a clean glass plate when every grain large enough to be visible can be seen at a glance.

DYNAMITE is any mixture of nitroglycerine with an absorbent, such as wood pulp, sawdust, infusorial earth, etc., so as to form a solid substance that may be readily handled with comparative safety.

THE creation of a forest reserve does not withdraw the tract from entry by the prospector. Mines may be sought, developed, equipped and worked in a forest reserve the same as in any other part of the public domain.

AN ore carrying a very high percentage of sulphurets may be concentrated without difficulty if a sufficient number of machines be provided to properly accomplish the work. No concentrator works well with an overload.

THE metal tantalum is now being used in making filaments for incandescent electric lamps. The weight of the filament is 22 milligrams. It is claimed that it produces a light equal to carbon filaments with half the current.

THE first shaft sunk on the Tamarack copper mine, near the Calumet & Hecla, in the Lake Superior, Mich., region, cut the lode at a depth of 2300 feet. The shaft cost \$200,000. It has since been sunk to a depth of about 3200 feet.

THE flow of water from a tank through a pipe may be increased without enlarging the tank by placing a bell-shaped piece on the end of the pipe entering the tank. This decreases the frictional resistance at the point of entry of the water.

THE Supreme Court of California has decided (case of Cameron v. Burnham, Sec. 1439) that in a mining partnership all parties to the agreement must live up to its conditions, and, failing in this, those who do not perform their part of the contract have no equity in the result.

A DISTINCTION is usually made between a settling tank and a classifier. The former is filled by the heavier material settling in the tank, the slimes overflowing. The classifier operates continuously, the coarser material passing out at the bottom and the fine overflowing at the top.

IT is unsafe to enter any disused mine shaft or other working without first testing the air by means of a lighted candle. Carbonic acid gas may fill the workings and be at first unnoticed. When the percentage of this deadly gas is large enough it is very prompt in its effect on men and animals.

IN drilling oil or other wells, the top of which must be beneath the water, it is customary to sink a casing larger than that required for the drill hole, and forcing it down into the bedrock as far as possible, shutting out the surface water. The drilling is then proceeded with in the usual manner.

AIR does not become liquid by reason of pressure, no matter how great, until the critical temperature is reached. The compression of air always generates heat, but heat passes away by radiation. It is stated that air may be compressed as a gas until it is more dense than it is in the liquid state.

THERE is no book devoted wholly to the wet concentration of copper ores, although there is a large amount of literature on this subject, scattered through many books and in the transactions of various scientific societies. This branch of metallurgy comes under the general head of ore dressing, or concentration.

WHERE it is desired to build the roof of a furnace, or an arch of any kind, and lumber for false work is scarce or unobtainable, the form may be built under some circumstances by piling up rocks, sticks and earth in the proper shape and building on this. When completed the waste material of this improvised form may be removed.

A BARREL of crude petroleum contains 42 United States gallons. Seven barrels of oil weigh 2240 pounds. The heat units developed by crude California oil range from about 26,000 to 28,000 heat units per pound of oil. In burning oil little or no soot is deposited on the heat-

ing surface of the boiler, and the "efficiency" of the heat is high.

IN the excavation of limestone and shale in the shafts sunk at Niagara Falls, for power purposes, the cost of such work is stated to have been about \$3.50 per cubic yard. The pit sunk for the Canadian Niagara Power Co. is 570 feet long, 17.75 feet wide and 162 feet deep—a total of 60,636 cubic yards. The cost of this excavation was \$212,226.

WATER is freed from crude petroleum of low B. gravity by the addition of naphtha, which, making the oil more fluid, allows the water to settle to the bottom. This is done in laboratories in testing oils. In making this test the oil is kept at a temperature of about 100° F. for twenty-four hours, which facilitates the separation of water and sand from the oil.

ALL dry placer diggings originate from the degradation or erosion of veins and ore deposits containing the gold. A good payable placer district is not always a safe indication of a payable quartz district, for the reason that the gold in the rocks may occur in small seams and be so scattered as to make vein mining unprofitable, while the concentration of this scattered gold in a channel makes a rich pay streak.

GLYCERINE is sometimes used advantageously to prevent the formation of incrustations in steam boilers. Glycerine is said to increase the solubility of the various combinations of calcium, particularly the sulphate. When the amount of lime present becomes greater than can be held in solution it forms a gelatine composition, but this does not adhere to the boiler, and is not carried by the steam into the cylinders of the engine.

A NEW method of saving wooden poles has been developed in the construction of the new electricity works at Zurich, Switzerland, where ordinary telegraph poles are surrounded by sheets of wire netting and held a short space away from the wood by iron brackets. These in turn are covered with cement mortar 1½ to 2 inches thick. Poles of this kind are claimed to be cheaper than iron poles, and to be equally as durable.

SOME ores consist of both soft and hard material. If the values present greatly predominate in either character of ore, it may be treated by rather coarse crushing in rolls and the screening out of the soft material, which in a dry ore would be fine. Then either class containing the highest values may be selected for special treatment, the remainder being treated by some other method or discarded as waste. At Cripple Creek, Colo., something similar is done by washing and screening out the fines as they came from the mines.

WHEN a hoisting rope is to be replaced by another of either larger or smaller cross section, the sheave and idlers, if there are any, should be turned out, in order that any grooves worn by the former rope may not cut the new. Sometimes these grooves are very pronounced, just fitting the strands of the rope causing them. These grooves will not correspond to the strands of a rope of either greater or less diameter than the one making them. This condition is particularly noticeable in small sheaves placed at heads in the shaft.

WHERE a claim has been properly located and the assessment work done thereon, as required by law, for two years, if the owner of the claim fails the fourth year to do the work, and other parties enter and do the work without being authorized, this work will not inure to the benefit of the stranger, who has no interest in the title. If the title is allowed to lapse by reason of non-performance of assessment, then a stranger may enter and relocate the claim, and if the latter complies with the requirements of the law may hold the claim as against the original locator.

AURIFEROUS pyrite may be successfully concentrated by smelting in reverberatory furnaces, the gold being collected in copper "bottoms." This is the process generally employed at Swansea. In this process the ore is first roasted to eliminate the sulphur and also arsenic and antimony, if they be present; smelting for coarse metal or matte, with the addition of oxidized ores; roasting the matte; smelting the roasted matte, with pure oxidized ores for white metal; roasting and smelting the white metal for blister copper; refining the blister copper.

SALT is made from the waters of Great Salt Lake, Utah, and the product refined by a continuous process. It is ground and fed into a revolving cylinder, 6 feet in diameter and 30 feet long. Inside this cylinder is a second fixed cylinder of iron 14 inches diameter, which is charged with superheated steam. An exhaust fan carries away the water vapor and fine dust of magnesium chloride from the heated salt between the outer and inner cylinders. By this process the greater part of the magnesium chloride is eliminated, but for pure salt for table and other refined uses this process has to be repeated two or three times.

WHERE a superintendent of a mine for a company locates mining claims in the unoccupied public domain for himself or for others, he can hold the same as against the company. The fact that he is employed as superintendent of a mine for a company does not deprive him of

his rights as a private citizen. He may locate for himself or for others, and may sell any location made for himself. The fact that he made the statement that the locations were made in the interest of the company will not bind him, unless the company can show an agreement with the superintendent that he is to locate claims for the company for some substantial consideration.

WHERE two pipes are screwed into the bottom of a tank, each pipe of the same diameter but one of the pipes much longer than the other, the larger amount of water will flow in a given time from the longer pipe, though the longer pipe will retard the flow somewhat by reason of the greater frictional resistance. The amount of water that will be discharged through a pipe entering a tank or reservoir is determined by the "total head," which means the vertical distance from the surface of the water to the point of discharge. In long pipes the friction head may be considerable, particularly in those of small diameter.

A LARGER amount of bromine was produced in 1904 than ever before, in the United States the quantity being 879,312 pounds. For a number of years the domestic output has fluctuated between 400,000 and 500,000 pounds; this has been obtained by concentrating the bromides in the brine from the process of salt manufacture. The custom is to treat the bittern with sulphuric acid (forming hydrobromic acid), and using as oxidizing agents either chlorate of potash or manganese dioxide. The producing States in their order of importance are Michigan, West Virginia, Ohio and Pennsylvania, which engage about thirteen operating companies.

TOURMALINE is of many colors—pink, green, bluish, black, lilac and other shades. It is usually translucent, often transparent. This mineral has some optical properties which are made use of in the examination of some minerals. For this purpose the tourmaline is cut into plates and mounted in a frame, forming what is known as a polariscope. The mineral to be studied is placed between these plates and examined for what are known as interference figures. Such devices are of little use to the inexperienced. Polariscopes are also made from sections of crystals of Iceland spar (calcite). They are used in connection with microscopes for the determination of minerals, in transparent thin plates.

THE United States Geological Survey was organized in 1879. Prior to that date there had been four extensive surveys, carried on under Hayden, King, Powell and Wheeler. These were respectively the "Geological and Geographical Survey of the Territories," "Geological Survey of the Fortieth Parallel," "Geographical and Geological Surveys of the Rocky Mountain Region," and "Geographical Surveys West of the One Hundredth Meridian." A catalogue and index of these several surveys has been issued by the United States Geological Survey as Bulletin 222, which is for gratuitous distribution, but none of the reports of the above-mentioned surveys are available for distribution.

TIDE LANDS, that is, the lands along bay shores and along the ocean between high and low tide, belong to the State, and mineral claims cannot be acquired by private ownership under any of the general laws providing for the disposal of public lands. A mining claim cannot be so located as to extend below the line of high tide. In Alaska permits were granted by the Secretary of War to miners to maintain structures in the water and to work the beach sands below the high tide line at Nome and elsewhere on the coast. Some oil claims have been located on the coast in southern California, notably at Summerland in Santa Barbara county. In these instances permission to bore oil wells was obtained from the Secretary of War. These lands are the property of the State of California, but the occupants of these lands have remained undisturbed by the State, the only authority that could dispossess them.

WHERE B outfits F and E to locate and prospect mining claims, where the outfitter fulfills his part of the agreement, when the prospectors locate a mine a co-tenancy at once arises, with its attendant rights and obligations. "Lindley on Mines" says: "While there is no element of trust existing between tenants in common of mining property who are partners only for the purposes of exploration, in cases of 'grubstake,' or prospecting contracts, where discoveries are made, the prospector may take no unfair advantage of his associate in dealing with property. If he does he will be held to account for the profits derived from his unfair practices. During the life of the contract either party may, of course, purchase mining claims from his own funds and at his own risk without enabling the other to participate in the purchase." If F in the case above mentioned locates in his own name or in the names of others, it does not relieve him of his legal responsibility to B, who shares equally with him, according to the terms of this contract in all, not in only a portion of the claims located. If F sells a partnership claim for \$5000, B has the right to demand and recover his half of this sum, and could without doubt recover that sum from F, even though he had attempted to place the money beyond the reach of B by giving it to his wife. The strangers who might possibly hold the claims bought from F unless B sued to recover them, for the reason that F had no right to sell his (B's) interest in the property.

## Amalgamating Gold Ores.

Written for the MINING AND SCIENTIFIC PRESS by  
ALGERNON DEL MAR.

The familiar concept that each individual ore must be treated as an individual problem is a fundamental principle of the metallurgy of gold. It is hardly possible to formulate an accurate generalization of the best system to be pursued on any particular ore, by a few simple tests, for in actual practice different modes of treatment may produce equally good results, but certain facts gained by hard experience may be of use to those not having had the time or opportunity of personal research, and who may be so placed that a few hints would be acceptable. The ideas set forth were obtained from Western experience, so may not be applicable to ores of other countries, and are not infallible, for there are, no doubt, others equally well or better qualified to express opinions on the subject, and if their experiences can be drawn forth the object of this article will have been accomplished. We are all interested in the successful operation of each individual mine and the interchange of ideas on such an important subject, as the recovery of gold from its ores will surely help along the good work.

The personal equation plays as important a part in gold milling as in other walks of life. A millman must be honest and sober; his work embraces a knowledge of the principal mechanical arts—mechanics, engineering and carpentry, and at least an elementary idea of chemical reactions—besides which he should be a man of judgment and resourceful.

Each amalgamator usually has his individual methods of accomplishing what he considers the best results from a given ore, generally obtained by long practice in the district where he has worked, or it may be a system acquired from other mines which having proved of sufficient richness to pay well have had the halo of success cast over all their operations. It would therefore be heresy for any one in that district to inaugurate any different method.

My personal contact with the fraternity of "quick slingers" is that this system is generally forced upon them by the management, which, often ignorant of the subject, will give a ready ear to the numerous "old amalgamators" with which every district is infected.

I have a case in mind where two directors of a company, both "green," were jointly managing a property. One happened to have had the benefit of the instruction of an old-time raw-copper plate amalgamator, while the other had evidently collided with another antiquity, but of somewhat different ideas. We were priding ourselves upon how well the plates looked, and thinking how all our hard work would be appreciated; but, alas! the blow came when, within an interval of five minutes, the two directors individually examined the plates, and, with wise looks and grave faces, one informed me that the plates were "too soft" and the other that they were "too hard." "Home, Sweet Home," sounded very pleasant about that time, and, as the expression goes, "I hit the road," leaving my brother millman to do the conjuring trick of pleasing the dual management.

We will take for granted that the sizes of the screen openings are those best suited to the particular ore, that quicksilver is fed into the mortar and that the plates have an inclination of 1½ inch to the foot, this being an average grade and one suited to most ores, and that the plates are the width of the mortar. The question is now what sort of plates to use and what system of amalgamation will give the best results.

First, as to raw-copper or electro-silver-plated plates, the underlying principle is this: Plates which catch an abundance of amalgam and are kept hard may be of raw copper, such as both chuck block and back plates inside, and lip and splash plate outside the mortar. The former must in all cases be kept hard, to prevent scouring, and the latter should be hard, except where the chemical constituents of the ore cause fouling or discoloration, when they may be kept stiff and dressed over whenever the battery plates are brushed up.

The reason the lip plate had best be left to harden, not sprinkling any "quick" on at any time, is that if so treated it is a splendid indication of how the inside plates are doing.

Raw copper plates, when in good condition, with a thick coating of amalgam give a satisfactory amalgamating surface, but have the disadvantage of locking up quite a bit of gold, do not allow of one to judge of how the ore is doing from day to day, and are not so efficient as silvered plates for catching fine gold.

Silvered plates, on the whole, have the advantage of being better amalgamators than raw copper, can be cleaned off without seriously injuring the plate and are ready at once to begin their function as gold savers, and by the weight of amalgam taken off each day a close approximation of the value of the ore and the run up to date can be estimated.

Silver plates that have been badly treated, and have patches of copper exposed, can be temporarily kept in fair condition by a variety of chemicals, but

the only efficient method is to have the plates resilvered or a thick coating of amalgam kept over the spots. When amalgam is squeezed through canvas or buckskin in hot water it is thinned out and some very fine gold amalgam goes through the material. This fine amalgam will separate and settle on the bottom. The fine gold amalgam, if thoroughly rubbed into the desilverized spots, will form a nice smooth surface which, if kept sufficiently thick, will keep down the verdigris, and other spots which discolor the plates.

An old-timer imparted to my eager ear his method of treating silver plates. He said it never failed to cover up the bad spots. He used a mixture of spirits of salt (HCl) and nitric acid—or in other words, aqua regia—to dress the desilverized portions, and as long as the silver on the plates lasted the results were satisfactory, but the spots kept getting bigger and bigger, and when I saw them copper was evidently very cheap and silver at a big premium.

A good rule for dressing plates is to brush up with a stiff whisk broom whenever the upper 2 feet get fouled, and once a day under any circumstance. Some ores discolor plates so badly that every three hours the plates may require brushing over. On the other hand, other ores are remarkably free from objectionable constituents, but there is more or less grease coming from machine drills and other sources, so that it is best to hang up at least twice a day to go over the plates. After each dressing the amalgam should be smooth and evenly distributed, with no loose pieces on the plates. To prevent loss from such a source, the use of a cleanup box is recommended. This is a wooden box about 2 inches wide and 3 inches deep, which is as long as the width of the plates (43 to 54 inches). It is placed under the lip or edge of the last plate when dressing the plates or changing screens. Before dropping the stamps, if the plate is flushed off with the hose, all loose

Inside Plates of a Stamp Battery.

amalgam that would otherwise escape will be caught in this box. It is surprising the amount that may be saved by this simple expedient.

In connection with this subject, coarse gold will be considered as gold which, when amalgamated, offers some resistance to the current of pulp flowing over the plates, and fine gold as that which does not. Free gold ore is an ore in which the gold is free from chemical or mechanical combination, except with the gangue, from which it can be separated by crushing. A refractory ore is one in which the gold is either in chemical combination or is a mechanical mixture with bases or other minerals, such that these foreign substances have a deterrent effect upon the action of quicksilver.

The discharge of a stamp mill is the vertical distance between the top of the dies and the bottom of the screen opening, and not the screen area, as some think. We will consider below 4 inches a low discharge, above 7 inches a high discharge, and between 4 and 7 inches a medium discharge.

If we divide ores into "free and refractory" and "coarse and fine" as regards the gold particles, from the foregoing remarks we will try to form some generalizations, first explaining that by hard amalgam is meant that which cannot be rubbed up with a stiff brush, but requires the use of some hard instrument for its removal; stiff amalgam that which can be brushed up, but will not smooth out again except in lumps, and soft amalgam as between the last and that condition where the current of pulp will make an impression upon the amalgam gradually moving it toward the lower end of the plates, which state of fluidity should never be permitted to continue, if ever reached.

1. An ore in which the gold is free and coarse may have a low discharge, no inside plates, raw copper or

silvered battery plates; if the former, the upper portion of plate should be hard and lower portion stiff, and if the latter, the whole plate should be soft and the amalgam may be rubbed off every day, leaving a thin coating. If there is a lip plate, in both cases, it should be hard.

2. An ore in which the gold is free and fine will need a medium discharge, inside back plate not necessary, but a chuck block plate is advisable. The plates should be silvered and kept fairly soft. The plates should not be rubbed except on clean-up days, but brushed up with a whisk broom, the surplus amalgam taken off, leaving a good coating of amalgam as a ground work for future building up. The lip plate should be kept hard.

3. An ore in which the gold is refractory and coarse needs a medium to high discharge chuck block and back plates, silvered battery plates, which should be kept fairly soft, not rubbered, but all the coarse gold taken off with a brush, leaving a coating of amalgam. Lip plate kept hard.

4. An ore in which the gold is refractory and fine needs a high discharge, chuck block and back plates. The plates should be silvered and kept soft, the last 3 feet being rather stiff.

The amalgam should never be soft enough to move down the plates, nor should globules of mercury ("tears") be seen under any conditions. The plates should not be rubbered, but brushed up, the surplus amalgam taken off leaving a thick coating. Lip plates kept hard except where they foul easily when they are kept stiff, the scum or discoloration being taken off by lightly brushing over the surface.

The general conclusions are first raw copper should only be used for inside and lip plates, but may be used for battery plates when the gold is free and coarse. For all other conditions electroplated silver plates are preferred; second, no chemicals should be used on silvered plates unless absolutely necessary; third, silvered plates should never be allowed to get hard, while copper plates may; fourth, the more refractory the ore the higher the discharge; fifth, a coating of amalgam should always be left on the plates, and sixth, a millman must use care and judgment and not become a mere machine, following certain rules regardless of the condition of his plate. A fixed condition of the plates can only obtain when the character and value of the ore, the rate of crushing and the "silver" feed are constant and unvarying quantities.

## Reduction of Tin by Iron and Hydrochloric Acid.

In a paper contributed to the Washington State College, F. F. Flanders says:

The reduction of tin by iron and hydrochloric acid, with the subsequent addition of mercuric chloride, as a test for tin, is doubtless familiar to all analysts. The test, as commonly carried out, viz., allowing cold acid solution of tin and antimony to stand in contact with iron nails for three to four hours, filtering off the antimony and adding mercuric chloride to the filtrate, is open to serious objections. It was found in this laboratory that the test was sometimes given, even when no tin was present. This point has already been mentioned in literature (J. A. C. S. XXV., 876), and attributed to the action of certain compounds of carbon, formed from the carbon present in the iron nails usually employed.

The writer had occasion to investigate the test lately and found that by keeping the solution in contact with the nails at a boiling temperature for ten minutes a complete reduction was obtained and no action was produced on mercuric chloride in the absence of tin.

The modification is suggested both as a remedy for the trouble mentioned and as a time-saver.

## Uses for Bromine.

By far the larger part of the bromine produced, says the Chemical Engineer, is used by the manufacturing chemists, who market the bromides of potassium, sodium and ammonium among druggists and photographic supply houses. A small quantity of bromine is also used in the preparation of eosine (a phthalein coal-tar color), and also as a reagent (in a 10% solution of potassium bromide) for precipitating manganese from acetic solution, for the conversion of arsenious into arsenic acid, and for the detection of nickel in presence of cobalt in the potassium cyanide solution. Bromine dissolved in water makes an excellent disinfectant. Hope for expansion in consumption is centered in the larger use of bromination and bromocyanide processes of gold extraction, which are suggested as substitutes for chlorination and cyanidation.

BUILDINGS are now being constructed of reinforced concrete, ten stories in height. It is not positive that the building of structures of this magnitude from reinforced concrete has passed the experimental stage. Failures of concrete structures are generally traced to the use of too small a proportion of cement, for which sand has been substituted, being less expensive.

## Geology of Tonopah District, Nevada.

Ever since its discovery, Tonopah has been a district of more than ordinary interest. The unusual richness of its ores, the somewhat mysterious distribution of the ore shoots, as viewed by the non-scientific observer, and the peculiar geologic conditions existing there have all aided in making the Tonopah district attractive alike to the miner, the geologist and the capitalist. Last year was published a preliminary report on the geology of the district by the United States Geological Survey. The work was done by J. E. Spurr. At that time Mr. Spurr stated distinctly that it was only the result of a somewhat brief reconnaissance, and that the development of the mines of the district was insufficient to make the opinions as to the geological structure and conditions more than tentative. Within the past year Mr. Spurr has had an opportunity to again visit the Tonopah district, and as a result he has made some radical changes in his opinion of the geology of the region as related to the ore deposits. The latest report is embodied in Bulletin 260 of the United States Geological Survey entitled "Contributions to Economic Geology in 1904." The title of Mr. Spurr's new paper is "Development at Tonopah, Nev., During 1904." In part this latest addition to our knowledge of the Tonopah district is as follows:

Until recently there have been practically only three producing mines in the Tonopah district, although a number of others have shipped small quantities of ore. These producers have been the consolidated Mizpah and Valley View mines (Tonopah M. Co.), the Montana-Tonopah, near by, and the Belmont Co., whose properties are operated through the Desert Queen shaft. Recently, however, another mine, which ranks with those above mentioned, has been discovered and developed—the Tonopah Extension—and shipments of considerable amounts of ore have been begun.

**PROGRESS OF GEOLOGIC KNOWLEDGE.**—The prediction made in last year's report that new veins belonging to the productive period of the earlier andesite would probably be discovered underneath the later overlying lavas has been fulfilled during the past year by the discovery of several such veins. In the Montana-Tonopah, north of the first large vein discovered (the Montana vein), another large east-west vein has been discovered and developed. This vein contains large quantities of rich sulphide ore, and has been called the "Macdonald vein." West of the Montana-Tonopah mine the Tonopah Extension shaft has cut a similar rich and large vein in the earlier andesite, in a portion of the district which, while on the borders of the formerly known productive region, had not been shown to contain any valuable ores. This vein, encountered beneath the overlying later andesite, is as strong as any of the other first-class veins yet developed, and may, indeed, be the extension of some of the earlier known lodes. Besides these important discoveries, fragments of similar veins broken by intrusion or faulting, so as not to have at present as great economic value as the unbroken veins, and similar veins of smaller size have been encountered in other mines, such as the North Star, the Midway, and the Tonopah and California.

**COMPOSITION OF ORES.**—A preliminary account of the early andesite ores was given in the last report, in which it was shown that the primary ore was essentially a rich silver sulphide, black in color and often antimonial. Since that time W. F. Hillebrand of the Geological Survey has made a prolonged chemical investigation of the ores, which is of great interest, as it touches their origin and their commercial treatment. The primary sulphide ore taken from the Montana-Tonopah (Montana vein) has the following composition:

### ANALYSIS OF SULPHIDE ORE FROM THE MONTANA VEIN, MONTANA-TONOPAH MINE.

Siliceous matter	15.18
Gold	.72
Silver	25.92
Lead	6.21
Copper	1.32
Iron	9.87
Manganese	1.36
Zinc	5.84
Selenium	2.56
Tellurium	None
Arsenic	.92
Antimony	.92
Magnesia	1.49
Lime	3.70
Carbon dioxide	6.34
Sulphur	Not determined

**VEINS OF A LATER PERIOD THAN THE EARLIER ANDESITIC VEINS.**—In last year's report (Bull. U. S. Geol. Survey No. 225, p. 98), it was noted that while the most productive veins were connected with the earlier andesite eruption, yet the subsequent volcanic eruptions also were frequently accompanied by silicification and vein formation, although these veins are of minor economic importance. It was clear even at that time that the most abundant mineralization and silicification, besides that connected with the earlier andesite, had occurred subsequent to the intrusion and extrusion of a more siliceous rock of later age. This rock was referred to at that time as the "early"

rhyolite, and was indicated on the map accompanying that report as rhyolite breccia. In the final report this formation is somewhat more accurately classified as rhyolite-dacite, and is specifically referred to as the Tonopah rhyolite-dacite. In intrusive bodies of this rhyolite-dacite, especially near the contacts, and lying within either the intrusive or the intruded rock, but preferably in the former, bodies of quartz, more or less mineralized, are very common. At the time of writing last year's report the chief examples known were the veins of the Mizpah Extension, one vein in the Desert Queen shaft, and the mineralization found in the workings in the Kiug Tonopah and the Belle of Tonopah shaft. During the past year, however, most of the working mines in the central part of the district have developed large bodies of this rhyolite-dacite and have encountered in this connection many of the characteristic quartz veins of this period.

These veins may be large and may carry values. They are easily confounded with the veins of the earlier andesite, just as the silicified Tonopah rhyolite-dacite, in which they usually occur, may be confounded with certain highly silicified phases of the earlier andesite. Such veins have been encountered in the Belle of Tonopah, King Tonopah, Mizpah Extension, Desert Queen, North Star, Montana, Tonopah, Mizpah, Midway, MacNamara, West End, Tonopah Extension and Ohio-Tonopah. On account of their resemblance to the earlier andesite veins they have been the object of a good deal of exploration and development work, which, on the average, has been decidedly unprofitable.

**CHARACTERISTICS OF RHYOLITE-DACITE VEINS.**—The veins of this period are characterized everywhere by irregularity and by a lack of definition and persistence, though their size may locally be great. As a rule they are elongated and have the appearance of regular veins, but cannot be followed as far on either the strike or dip as can the regular veins. They may disappear by scattering and passing into a silicified wall rock, or they may be cut off along a cross fracture. The quartz is, as a rule, dense and jaspery and either white, gray or black in color, and is therefore usually different in appearance from the white quartz of the earlier andesite veins. The veins are commonly barren or contain only very small quantities of gold and silver, except locally, where rich bunches of ore may occur, though of limited and irregular extent. In the Ohio-Tonopah barite occurs as a gangue mineral with the rhyolite-dacite veins. This mineral has not yet been found in connection with the earlier andesite mineralization. In the Desert Queen and the North Star, where quartz of the rhyolite-dacite period has been opened by drifting, a green stain forms on the walls, which is a basic copper sulphate. This phenomenon has not yet been noted in connection with the earlier andesite mineralization. Characteristic of the rhyolite-dacite veins, to which, however, there are numerous exceptions, is the greater ratio of gold to silver in them as compared to that in the earlier andesite veins. In the latter class of veins the gold averages about two-fifths of the value, the silver three-fifths, while in the former class the gold is apt to exceed this amount and sometimes to occur with practically no silver, although the proportion is very changeable. Often, again, the proportion of gold and silver is the same as in the earlier andesite veins.

A favorite place for these veins is on the upper contact of a rhyolite-dacite sheet with overlying decomposed andesite. Such, for example, is the situation in the Mizpah Extension, the MacNamara, Tonopah Extension and West End, and to a less degree in the Ohio-Tonopah. This fact is explained by the conception that ascending hot waters circulating through the fractured rhyolite-dacite rose until at the contact with the overlying soft, decomposed andesite they found a partially impervious barrier, along whose lower contact they circulated and deposited the materials which they held in solution.

**EFFECT OF WATERS PRODUCING THE TONOPAH RHYOLITE-DACITE VEINS ON EARLIER FORMED VEINS.**—Although as a rule a decomposed andesite seems to have presented a formidable barrier to the circulating waters accompanying the Tonopah rhyolite-dacite, in some places the waters must have traversed the andesite. Indeed, it is along the brittle andesite veins and silicified adjacent andesite that fractures and fissures must have been most easily formed at this period. In the case of the Tonopah Extension, the earlier andesite vein has been reopened, and along the hanging wall a new vein of barren jaspery quartz formed. This is probably due to waters of the rhyolite-dacite period of mineralization. In this case the new quartz is relatively barren as compared with the old. It is evident, however, that the effect of such solutions must have been to dissolve a great deal of the gold and silver contained in the earlier veins, and naturally to reprecipitate it elsewhere. Thus the ores might be reprecipitated in a concentrated form. This very likely has been the case in the Montana-Tonopah, where the original vein has been reopened, and in the fissure thus formed minerals similar to those in the older vein, but richer in gold and silver, have been precipitated in crustified form. It is reasonable to assume that this may have been the work of the waters of the rhyolite-dacite period, of the same kind and character as those to which the barren quartz hanging wall portion of the vein in the Tonopah Extension is due.

Again, it is natural that such waters may have dissolved some of the metallic contents of the older veins, and instead of precipitating them within these veins may have carried them out and deposited them elsewhere, as, for example, in the veins of the rhyolite-dacite, forming bunches of high-grade ore in these usually barren veins. This may be the explanation of the comparatively small amount of rich ore found in some of the rhyolite-dacite veins, as, for instance, in the Desert Queen and the MacNamara. These are practically the only veins of this period in the district that contain high-grade ore, and both these veins lie near rich earlier andesite veins. Veins in the rhyolite-dacite that lie farther away from the earlier andesite veins are frequently large, but are typically of low grade or barren.

These veins are plainly the results of ascending hot waters, and represent the effects of the Tonopah rhyolite-dacite eruptions, having the same relation to these eruptions that the earlier andesite veins did to the eruptions of the earlier andesite. The characteristic lack of definition and persistence in these veins as compared with the veins in the earlier andesite shows that at the time they were formed no definite fracture zones were available as channels, so that the ascending waters had to force themselves up along irregular courses. This mineralization is probably the same in time, nature and origin as that at Gold Mountain, which is 4 miles south of Tonopah, and may very likely be the same as that in the newly discovered camp of Goldfield, which lies about 23½ miles south of Tonopah.

**PROGRESS OF KNOWLEDGE OF UNDERGROUND FORMATIONS.**—It was explained last year that the geology at Tonopah was so complex that no accurate detailed knowledge sufficient to guide mining operations with certainty could be obtained far from the regions which have been explored underground by mine workings, and it was pointed out that with the increase in number of such workings the chances for successful mining in the immediate contiguous regions could be progressively more closely estimated. It has indeed turned out to be true that the developments of the past year have had this effect in adding to our knowledge of underground geology and in increasing our basis for future estimates. The actually productive area has been slightly but not greatly enlarged, and within this area, as previously mentioned, most of the mine workings have encountered serious drawbacks to successful mining in the shape of large and irregular bodies of the later and intrusive Tonopah rhyolite-dacite. These bodies do not come to the surface over most of the area, and their presence could not have been accurately foretold, although the probability that such intrusions would be encountered anywhere and everywhere was pointed out by the writer in his previous report. The complexity of the intrusions was not exaggerated in the ideal cross-section previously published.

Besides the intrusions of later eruptives, cutting off the earlier formed andesitic veins, the complicated faulting, characteristic of the district, which, in the early history of its development, made the Fraction vein practically impossible to follow and to exploit economically, has been found to manifest its effects in the other veins, entailing more or less serious hindrance to mining operations. The Mizpah vein is not only broken in detail by minor faults, but is cut off to the east, the west, and at the bottom by faults of greater magnitude. Within the important and rich veins of the Montana-Tonopah complicated faulting has operated so as to displace the ore bodies in a very puzzling way. These faults have different systems and their effect is too complicated for explanation within a short space, but they are explained more at length in the final report. The Tonopah Extension vein, up to the time of examination by the writer, had continued to be unusually free from faulting.

Outside of the known productive area exploration has been continued in those formations and in those portions of the district which were found by the writer to be more favorable than the rest. The chief work has been done east and west of the productive region, but it cannot be said that so far the results are highly gratifying. To the east the Halifax shaft has been pushed down to a depth of 800 feet and is in the later andesite from top to bottom. Work has been continued on the Rescue shaft, which is in a white rhyolite volcanic neck. Work in which a larger amount of hope could perhaps have been reasonably placed has been carried on in the area west of the productive region. In this area, as already noted, the Tonopah Extension has been successful, while the other workings have developed nothing of importance. The Ohio-Tonopah shaft, 770 feet deep, encountered a large body of the Tonopah rhyolite-dacite, and in this most of the drifting was done. The Golden Anchor shaft, situated in as favorable a position as could be chosen in this neighborhood, has reached a depth of 640 feet without definite developments. This shaft is mostly in the later andesite, with some rhyolite-dacite near the lower portion. Farther west, near the western limit of the area shown on the published geologic map, the new Pittsburgh shaft was, at the time of the writer's visit, in November, 1904, 570 feet deep in soft volcanic breccia belonging to a period later than the ore-bearing formations. North of this point, but also on the edge of the area mapped, the Little Tonopah shaft was at

that time 585 feet deep, and its bottom was still in the later andesite.

**SUMMARY.**—The Tonopah veins are similar in nature, composition and origin to those found in some of the richest mining districts, such as the Comstock of Nevada and the Pachuca in Mexico. Indeed, it is probable that all of these districts and many others lie within a single petrographic and metallographic province characterized by similar rocks and similar veins formed at similar periods. In the Tonopah district the rich ores occur in the veins in the shape of irregular shoots or masses (bonanzas), comparable in size and richness to the famous bonanzas of the districts mentioned. The geological conditions also indicate that such bonanzas were formed down to considerable depths. These are the striking advantages of the district, which have justified considerable expenditure of money in exploration.

The disadvantage of cost of production is common to all mines in the desert region, and if this were the only drawback the production of the district might reasonably be expected to become enormous. A greater disadvantage, however, as previously pointed out, consists in the disturbances to which the veins have been subjected since their formation. These disturbances consist of both repeated and copious intrusions of later volcanic rocks and of faulting which accompanied the intrusions, forming a condition illustrated in the ideal cross section published last year.

By these disturbances the veins have been broken in detail, and sometimes even displaced to such an extent that search for their continuation is practically hopeless. In mining, the expense of following the vein is increased by slight disturbances, and where the vein is greatly displaced a large amount of money must be spent in exploration, however intelligently this may be directed. When veins belonging to one of the later periods, especially that following the Tonopah rhyolite-dacite intrusion, are encountered, it may be difficult for the mining man to identify their character or class, and much expense is incurred in drifting along these in search of ore bodies, which, if encountered, are usually not sufficient to pay for the whole work done.

Moreover, the exploratory shafts which have been sunk, particularly during the last year, in the region around the productive area indicate that the earlier andesite, with its productive veins, if, indeed, it can be found in any large amount in these regions, lies under an average great thickness of the subsequent barren formations. Where these veins are very close to the surface, as in the present chief productive area, the difficulties of mining, as pointed out, are still so great as to make large profits often a matter of considerable doubt; and where similar mining and exploration must be carried on at an increasingly greater depth it becomes more and more doubtful whether the results will warrant the necessary outlay.

For these reasons, in considering the balance struck between the highly advantageous character of the ore and the origin and nature of the veins, and the disadvantageous circumstances introduced by late disturbances, it impresses the writer that the balance is at present rather on the disadvantageous side.

### Automatic Water Gauge.

Where gauge glasses are provided on locomotives, the engineers frequently throw them out of service and depend entirely on their try-cocks to inform themselves as to the water line in the boiler, the excuse being that the danger from a broken glass is greater than from anything else around a locomotive; and although it is seldom that satisfactory evidence can be found, it is almost certain that the majority of locomotive boiler explosions are caused by low water.

In the Shallow gauge, as illustrated, the automatic

valve is not subjected to wear only when it is closed through the breaking of a glass, and as this is only at widely separated intervals, there can be no appreciable wear for years. The whole valve is constructed

of brass, with the design that no trouble be experienced from the collecting of sediment or scale and the consequent sticking of the valve.

The Shallow gauge is furnished by W. S. Haines, 136 S. Fourth street, Philadelphia, Pa.

### Mining in Korea.\*

Korea has vast and only partially developed mineral resources. With the settlement of the political difficulties which at present embarrass the progress of that country, it may be expected that these resources will receive more attention than in the past. At present the largest mining concern operating in Korea is the Oriental Consolidated Mining Co., an American organization, with offices in San Francisco, Cal. This company controls a large concession throughout which are mineral veins of greater or less value. Several of these veins have been extensively developed and equipped with modern machinery. Among the most important are the Chittababie mine, equipped with a 20-stamp mill, which started up in 1897; the Tabowie mine with a 40-stamp mill, which was completed in August, 1899; the Kuk San Dong mines (north and south), also

Cross Section Illinois Mine, Wisconsin.

equipped with a 20-stamp mill, to which it is intended to add twenty stamps. This extension of plant has been postponed for some time past, due to the war. The Charabowie and Maibong mines are equipped with a 40-stamp mill, which started up February, 1902. This mill is illustrated in one of the accompanying engravings. The Taracol mine is one of the most important of the company's holdings and is equipped with an 80-stamp mill, also illustrated, (see front page), and which was started in March, 1903. This gives this company's mines a total of 200 stamps. These mills crush on an average over 160,000 tons of ore annually, which, according to the official annual report of the manager, averages about \$6 per ton. For various reasons there has been considerable loss of time in the running of these mills.

The stamp duty at the various mills ranges between 3.1 tons and 4.1 tons daily. The several mills

accompanying illustrations are furnished. W. Deane, assisted by Elvin Wilcox, is putting in an extensive hydro-electric plant for the Oriental Co., and E. Poage is in charge of the dam. It is expected that the dam will be completed this year. The reservoir site is the Chorie valley, which will afford a large reserve. It is the intention, by way of experiment, to stock the reservoir with American trout, for which the Fish Commission has agreed to supply the necessary stock. Under existing conditions mining in this part of the Orient is not all that an American may desire, but the mines of the Oriental Co., while subjected to many annoyances, have not met with any serious losses as yet, and have been able to operate on nearly full time.

### Value of Geological Knowledge.

Written for the MINING AND SCIENTIFIC PRESS.

A knowledge of geology often saves the miner much annoyance, much loss and useless expenditure of time. It is true, without doubt, that the greater number of discoveries of prospects which eventually become mines are made by prospectors who have only a limited knowledge of geology, but this does

not prove nor indicate that those having such geological knowledge would not be likely to have made the discoveries made by others. As a rule, those who have an expert or even a fair knowledge of the science of rock formations are engaged in some pursuit affording a more certain result than that upon which the prospector can depend.

It is usually after the location discovered by the prospector has developed into a mine that the services of the geologist become valuable. His knowledge may then be of value in determining how development work should be directed. It is often as important to know what not to do as it is to know what should be done in a mine.

The writer once knew a successful prospector who had discovered a prospect and was developing it as well as his limited means would admit. He finally decided that the only way to find the main ore body

Forty-Stamp Mill, Maibong Mine, Korea.

are equipped with concentrators and cyanide plants, and many improvements have been and are still being made. The war has caused many stoppages and has increased the cost of production materially. H. F. Meserve is manager. Each large camp has a separate superintendent. The San Francisco representative is J. S. Wallace, through whose courtesy the

\* See illustrations on front page.

and to get into the payable ore in quantity was by sinking a shaft. He expressed his intention to another miner who had some geological knowledge. The latter at once assured the prospector that to do so would only result in disappointment, as the shaft would in a few feet pass out of the ore-bearing formation into barren porphyry. The prospector was advised to drift to the west, as in that direction

lay his only hope for improvement. Following this advice the prospector ran a crosscut westerly and in less than 10 feet had opened a 4-foot vein of pay rock. Had he followed his own inclination he would have exhausted his resources, found nothing and probably abandoned the claim.

The accompanying sketch shows what is really a simple geological situation, and yet the prospector, unfamiliar with existing geological conditions, would scarcely dream of an ore deposit underlying the glacial drift and sandstone. Geologists of experience had studied the surrounding region, the Baraboo range in Wisconsin, and although there is no mineral outcrop, their knowledge of geology enabled them to intelligently locate the bore hole which resulted in the discovery of the ore deposit which made the Illinois iron mine. Not only were the strata largely covered with glacial drift, but there were other drawbacks to mining operations there. Here again a knowledge of the geological structure enabled the engineers to overcome these difficulties.

At the Illinois mine, after attempts to sink the shaft through sandstone, it was decided to penetrate the footwall slate by a shaft dipping 60° north and to crosscut the ore through the underlying strata. After reaching the iron formation at a depth of 30 feet, but little water was encountered, and still less after the latter was reached, at a depth of 100 feet. In mining the ore above the first level more water is encountered than from below on account of the proximity of the sandstone. The amount of ground water in the crystalline rocks associated with the ore in the Illinois mine is comparatively small, the movement being entirely through irregular fractures pervading the formations. In the near vicinity of the contact with the overlying sandstone, within 50 or 65 feet, many of the rock openings extend to the sandstone, and water is abundant. The ground water level in the valley is generally within a few feet of the surface.

At Leadville, Colorado, numerous rich strikes have been made the past year, largely due to a knowledge of the structural geology of the district, and the characteristics of the ore bodies.

## Experiments on Ore Sampling.\*

Written by A. T. FRENCH.

The following notes relate to the reduction of samples from about 100 pounds weight to 5 to 10 pounds, a quantity suitable for grinding down in the laboratory. The well-known process of coning and quartering undoubtedly gives satisfactory results, but it is a slow and rather tedious operation. Among others, the following two methods have been proposed with a view to saving time:

(a) THE "CANVAS" METHOD.—In this the principle is the same as in the coning and quartering method, but time is saved by using a sheet of stout canvas about 6 feet square, instead of or better upon the usual iron plate. The breaking up, when a suitable ore crusher is not available, is done with hammers on an old casting or a block of hard stone placed on the canvas, and when sufficiently small the sample is mixed by rolling from end to end of the canvas. Finally it is brought to the center of the canvas, the four corners of which are gathered together and shaken to detach any fine dust, and the sample is then divided into four, and two opposite quarters taken away in the usual manner. The two remaining quarters are mixed as before by rolling and the process repeated any desired number of times.

(b) THE "ALTERNATE SHOVEL" METHOD.—The sample is broken up on an iron plate, shoveled into a cone and mixed thoroughly by shoveling over twice, always forming a cone and placing every shovelful upon its apex. The cone is then shoveled again, every alternate shovelful being kept and the rest rejected. The new cone thus formed is reduced in the same way any desired number of times, further mixing being unnecessary except after breaking up again. There are always some fines left on the plate after shoveling. These are swept into a heap and carefully divided, half being placed on the apex of the cone and half thrown away. When the sample is not more than 20 to 30 pounds weight it is better to use a small scoop holding ½ pound or so of the mineral. In order to test these two processes, a number of samples were divided into two portions, some by method a and some by method b, and the two portions treated as separate samples, being further divided until about 6 pounds of each were left. These were then broken up in the laboratory and carefully assayed for copper. The ore on which these experiments were carried out was a pyrites, carrying chalcopyrite, with a highly siliceous gangue. When broken up, the fines were very much richer than the coarser

material. The samples averaged about 100 pounds in weight and had been crushed to 1½ to 2-inch cubes through a rock breaker. They were then broken down by hand to about 1-inch cubes and divided twice by the method chosen, giving two 25-pound samples. These were further broken down to about ½-inch cubes and divided twice more, giving the final samples for the laboratory. Results were as follows on eight samples:

	METHOD A.		—Canvas Method—	
	Original.	Duplicate.	Original.	Duplicate.
Copper, %	2.90	2.85	3.67	3.57
	3.48	3.48	3.48	3.48
	10.90	10.70		
	METHOD B.		—Alt. Shovel Method—	
	Original.	Duplicate.	Original.	Duplicate.
Copper, %	2.90	2.85	3.67	3.57
	3.48	3.48	3.48	3.48
	10.90	10.70		

From the above it will be seen that the "canvas" method gives the best results, especially when dealing with rich ore.

For a further test six bags of 9% to 10% of the ore were treated, two by method a, two by method b, and two more, for comparison, by the coning and quartering method. The times were also taken, and were, exclusive of breaking up the samples:

	Av. Min.
Method A.....	21
Method B.....	18
Coning and quartering.....	27

Results were as follows:

—METHOD A—		—METHOD B—		Coning & Quartering Method.	
Canvas Method.		Alt. Shovel Method.		Orig.	Dup.
Orig.	Dup.	Orig.	Dup.	Orig.	Dup.
8.97	9.07	9.45	8.67	8.87	8.77
9.83	9.70†	9.96	10.07	9.02	9.00

This second series of experiments, then, confirms the first, showing that the "canvas" method is more reliable than the "alternate shovel," and that it has about the same degree of accuracy as the "coning and quartering" method, while taking nearly a quarter less time.

It having been suggested that the fines might stick to the canvas and thus collect in the portion kept, enriching it at the expense of the "rejections," in this case the whole of the rejections from the two duplicate portions of the original sample were saved, broken down small on an iron plate, and divided down by the coning and quartering method. This sample assayed 9.90—0.1% higher than the average of the other two.

## Prospecting for Desert Mines.

Ever since the venturesome argonauts first crossed the plains and mountains from the East, seeking fortune in the great, undeveloped and unknown West, the desert region of the western United States has had a sort of fascination for the prospector. It is a land of marvels. It contains strange minerals, rich mines, a flora and fauna all its own, and climatic conditions not found elsewhere. Men who have spent many weeks on these arid wastes came in time to

panion of the prospector on these venturesome trips is either the sturdy broncho horse, raised on desert ranches, or the even more hardy burro. The latter requires less fodder, less water, and on the whole less care than the horse, and is generally more tractable. He packs the miner's outfit of tools, grub and water, and together they share the hardships and in a small measure, the benefits of the trip. The accompanying illustration shows the manner of packing the burro as a water carrier on the Mojave desert of California. Without him life would be all but impossible to the prospector, before a permanent camp is established, from which it is safe to radiate in all directions in search of prospects. In the early days on these great Western deserts many "pilgrims" lost their lives. In almost every case these deaths occurred from lack of water and the unfortunate men and women met their fate in the valleys. As the country became better known it was learned that there was often a better prospect for water by going into the hills. There springs were occasionally found, or water had accumulated in natural depressions in the canyon bottoms (called by the miners tanks) from the infrequent rains.

All desert travelers know how easy it is to pass a good spring of water and not see it at all. There are many places where large springs break out from rock ledges and flow a few yards, to be wholly absorbed by the sands. A traveler may pass sometimes within 100 feet of one of these springs and see no sign of it. Old Woman's springs, 45 miles east of Victorville, San Bernardino county, Cal., is a case in point. There is a spring discharging about fifty gallons of good water per minute, and yet one may pass within 100 feet of it on the bluff above and never suspect its existence. Paradise spring in San Bernardino county, Cal., north of the Calico range, is a few hundred yards off a main traveled road and would not be suspected by a passing traveler who did not know of its existence. These are but two of a score of similar instances known to the writer occurring in Utah, Nevada, Arizona and California. Notwithstanding its many drawbacks, there is a charm about the desert which is almost irresistible. The atmosphere is clear and pure, and although the heat and metallic glare of the day are at times almost unbearable, its cool nights are refreshing and invigorating; its sunrises are gorgeous, and its sunsets indescribable. Slowly the deserts are being reclaimed. Railroads have been built across them and still others are building. Vast areas are coming under cultivation by means of irrigation, and the springing up of prosperous mining camps will do much to rob the desert of its terrors, both real and imaginary. All this radical change is due to mining. The possibility of finding mines at first induces the prospector with his burro to penetrate the vast wilderness. The development and operation of the veins he finds gives employment to thousands of men, and cities spring into existence as a natural consequence. This offers an inducement to capital to construct railroads, and the large communities thus formed and existing make the tilling of the land advantageous wherever water can be obtained for the purpose of irrigation. It cannot be anticipated that climatic conditions will materially change, though there is abundant evidence

A Desert Camp With Water Train.

admire its vast solitude, its rugged mountains, its trackless valleys — trackless because often well-known roads and trails are wholly obliterated in a few minutes by the driving winds which sweep across the plains, whirling great clouds of sand and dust high in the air, shifting good-sized hills of sand from one position to another. The prospector goes out into the desert region with little if any misgiving as to his ability to safely return and perchance to find his fortune in the form of a rich mine. Others have done it before, and each prospector feels sanguine of his own success, and believes in his luck. The com-

of other conditions than those now existing having obtained on the desert in the past, and that within comparatively recent time. Great cottonwood logs are found buried in the sands of some basins, a few feet below the surface, where no living trees now exist. Lake beds have been filled with sand washed in by the deluges of rain which fall from time to time, and there are numerous indications that the rainfall is now less than it formerly was on some of these desert valleys. Whether the present conditions of nature will improve or grow worse for the habitation of mankind remains to be seen.

\*Bull. of Inst. of Min. and Met.

## Mining and Metallurgical Patents.

PATENTS ISSUED MAY 30, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINERAL RECLAIMER AND SAVER.—No. 790,913; H. L. Orr and F. B. Finley, Fort Collins, Colo.

In apparatus of class described, tank divided into plurality of compartments of different sizes, each containing filtering medium, screen arranged in larger compartment, automatically operating means for maintaining level of liquid within tank, trough arranged below screen, filtering medium arranged adjacent to larger compartment, and communication between trough and latter compartment.

TUBE MILL.—No. 790,927; G. H. Sharp, Jonesville, Mich.

In tube mill, horizontal, rotatory cylinder having inlet and outlet orifices, interior, wooden grinding surface and arranged to contain mass of grinding bodies, cylinder having set of longitudinally extending, helical shelves secured therein and arranged to lift contents of cylinder and drop them during its rotation, inclination of shelves tending to retain grinding bodies near inlet orifice.

JET NOZZLE FOR WET CONCENTRATORS.—No. 791,387; J. L. Weaver, Boise, Idaho.

Jet nozzle for wet concentrators provided with parallel elongated discharge openings, and contracting passages leading thereto, formed by converging walls inclined from perpendicular and inner wall of each passage having greater angle than outer wall, whereby water is discharged in sheets diverging from nozzle.

WATERPROOF EXPLOSIVE CAP FOR BLASTING PURPOSES.—No. 791,100; E. W. Keith, Denver, and A. H. Boyd, Leadville, Colo.

In fuse and explosive caps, combination of shell charged with charge of explosive material in bottom portion, gasket or disk-shaped ring of soft rubber adapted to be dropped loosely in shell on top and against covering of explosive charge, fuse adapted to

be inserted in shell against top of ring-shaped gasket, and indentations in entrance edge of cap arranged to clamp fuse to cap and under pressure against top of gasket.

CAM.—No. 791,043; G. S. McLeod, Phillipsburg, Mont.

In cam, combination with hub member having flat outer face, of shoe member having outer curved face and opposite flat inner face extending longitudinally of same and to opposite ends of curved face and adapted to rest against face of hub member, one of members having longitudinal recess in flat face and other member having longitudinal rib that is arranged to engage in recess.

MINER'S LAMP HOLDER AND HEAD PROTECTOR.—No. 791,231; I. Wantling and S. Doubet, Peoria, Ill.

In combination with cap, lamp holder consisting of plate secured to cap its side edges intumed, second plate having side edges secured under intumed portions of first mentioned plate, and body of second plate provided with crimped portions forming air passage between two plates for circulation of air, and second plate having central body portion concave.

ELECTROLYTIC DEPOSITION OF METALS.—No. 791,341; H. C. Harrison, London, and J. Day, Weston-super-Mare, England.

Method for effecting, with high current density, rapid electro-deposit of tough and homogeneous metal with smooth surface, which consists in simultaneously revolving cathode and directing tangentially all around vertically mounted cathode, so as to approach surface of cathode tangentially and cause swirl of electrolyte at all points around cathode and throughout length thereof, series of jets arranged certain distances apart, whereby rapid and continuous change of electrolyte immediately contiguous throughout length of and all around such surface of cathode is effected.

PROCESS OF EXTRACTING ZINC FROM ITS ORES.—No. 791,401; A. G. Betts, Troy, N. Y.

Process of extracting zinc from ores which consists in dissolving zinc therefrom as solution of zinc sulphate, electrolyzing solution with liquid metal cathode for production of zinc alloy, and electrolytically extracting zinc from alloy and depositing zinc on suitable cathode.

ART OF SEPARATING GOLD OR OTHER DIAMAGNETIC METALS.—No. 791,305; L. T. Weiss, New York, N. Y.

Herein described process of separating solid particles of diamagnetic metal from accompanying matter, which consists in first coating with magnetic metal by electrolysis such diamagnetic particles and separating such coated metallic particles from accompanying matter by magnetic means.

CONCENTRATOR.—No. 791,200; C. O. Michaelsen, Salt Lake City, Utah.

Double-floored concentrating table adapted to oscillate in any direction and consisting of longitudinally inclined upper and lower floors within upwardly projecting sides, with space between two floors, upper floor provided at upper end with adjustable transverse openings communicating with lower floor which is also provided with adjustable transverse openings at lower end communicating with box chute for conveying water and pulp to lower table located under double table, lower table inclining in opposite direction from pitch of double table which is actuated by means of two bolsters, pivoted to table at points midway of its longitudinal direction, bolsters being pivoted at each end to pins of cranks forming part of articulation, in such manner that when articulation are adjusted and operated by suitable means, desired movement will be imparted to bolsters, and through them to table, each of tables being independently adjustable as to inclination.

BIT FOR ROCK DRILLS.—No. 791,264; M. Hardsocg, Ottumwa, Iowa.

In combination with bit provided with longitudinally extending passage on interior opening through cutting face, socket provided with shank adapted for insertion in pneumatic tool, shank being provided with longitudinally extending passage adapted to communicate with passage in bit, and series of radially arranged diverged openings leading from longitudinal passage and adapted to discharge excess of exhaust air.

## Thirty Days of a Mining Engineer's Life in Mexico.

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by  
E. A. H. TAYLOR.

Much to our disgust within half an hour it cleared up completely and the night was clear and cold. By daylight we were on the road again and had hardly gotten well under way when it clouded up rapidly, and almost immediately sleet began to fall, driven by a sharp, cold wind. The sleet turned to snow, and alternating between snow, sleet and rain, accompanied by a piercing wind, it kept up for forty-eight hours with but few intermissions.

We dropped down a mountain side into a little valley, where we found a projecting ledge of rock, and being far from comfortable myself, and noting that my mozo must be suffering, I decided to camp. By the time we had unpacked and stored our baggage and got a fire started we were nearly frozen, but after getting breakfast were all right.

That night we slept under the ledge, but there was hardly room, and during a heavy shower during the night the water dripped down on my bed, and I awoke to find one-half of my bedding well soaked. Once in the night it cleared up, but awakening at daylight I found the trees covered with snow, but as it was raining then in half an hour it all had disappeared. And so broke the day of April 1, 1905.

It clearing up a little by 9 A. M. we got under way, traveling three hours in all kinds of weather until we reached a ranch called "Vuelas del Rio." Here we stayed until the next morning. About dusk that evening the Federal mail went by—four sacks packed on a mule driven by a native on foot—who, as the creeks were up, had stripped himself to jumper and drawers, these last being rolled up as high as he could get them, and bare legged, thinly clad, was running along behind, keeping his mule on the trot. I was standing by a fire, well huddled up in my overcoat, and was none too comfortable. How must the mail carrier have been? It was sleeting then, but with a hearty "adios" he trotted by, making for a little ranch 3 miles above.

The next morning broke clear and crisp, the world being dressed in white. We got an early start in spite of the cold, and nearly froze for two hours until the sun got well up. The country was rough and rocky and the coating of ice and snow made traveling dangerous, as the foothold for the mules was none too secure. However, we had no mishap, and by noon the world was bright and gay and the weather delightful. Just before noon we went over the highest range on the route, 8700 feet above sea level. By 4 P. M. we had dropped down into the "Valle de Topia"—the headwaters of the Humaya river—and were only 3700 feet above sea level. In the morning we were surrounded by ice and snow, and here we had roses and oranges in bloom, and alongside peach and apricot trees loaded with green, half grown fruit. We forded the river, deep and swift, and climbing over a ridge dropped down into the little mining camp of San Bernabe.

From Tepehuanes to El Valle the formation consists of tuffs and agglomerates from 1000 to at least 3000 feet thick. Here in the valley the first solid rock is disclosed—andesite—and at San Bernabe it is crossed by silver-bearing ledges.

We reached San Bernabe just at dusk and were cordially received by the owner of the house where we applied for permission to stop, he apologizing to us for the lack of accommodations.

The altitude at San Bernabe is about 4000 feet, and the temperature was quite in contrast to what we had enjoyed (?) the night before. We slept under the little porch, tying our mules to the posts of the same. Here man and beast fed well and rested well, and at break of day the next morning we took our leave and started to climb the mountain, over which we had to go in order to reach Topia. We climbed steadily for just two and one-half hours and on the summit were 7000 feet above sea level. Here we found remains of snow and some ice, and as we began to ride down the valley to the west the stream got deeper and deeper.

Here also we noted the effects of the recent storm, as in many places the road was obstructed by fallen trees. The tuffaceous summits of the Sierras are well timbered, although the timber is mostly of small size—12 to 16 inches in diameter and 80 feet high. This is not surprising, as there is no soil, the trees holding themselves in or on the porous rock. Even the pines can penetrate this but a few feet, and in many parts the surface is a network of roots running in all directions. The tufa being soft and porous absorbs water in the rainy season, and here the pines find a place to root and grow. The more compact rocks, not absorbing moisture, and the thin soil covering them soon drying out, accounts for the lack of timber around most mining camps in Mexico.

The frequent forest fires and the lack of soil on the tufa mesas and ridges account for the small size of the timber encountered as a rule.

It took us one hour of continuous climbing to reach the edge of the tufa cap, and I noted several mines

in exploitation as we climbed, one reaching up to the contact.

Once on top we found ourselves on a mesa covered with more soil than is usually found in the Sierras, and here the growth of pines was the finest I have ever seen in Mexico. For half an hour we rode down a valley that gradually narrowed to a canyon, through which roared an almost impassable torrent. Suddenly we came to the edge of a precipice and the valley of Topia was at our feet. The town was about 5 miles away and 1000 feet lower, but it took us one hour and thirty-five minutes to reach it. The road leading down into Topia from the summit is a typical mountain trail, and is very steep and very rough for the first mile; and in many places is built up for 20 feet or more in height, and is paved with rough boulders for long stretches as it meanders back and forth along the face of the tufa bluff.

Topia is a very important lead-silver mining camp. The formation here is andesite. It is located at the head of a valley, 5500 feet above sea level, and is surrounded on three sides by bluffs, the tufa capping over the andesite. This cap surrounding Topia varies from 200 to 1000 feet, it being thinnest at the back of the town, to the north, where the andesite rises up nearly through it.

Topia has had hopes of a railroad from the coast, but there being no outlet to the east, it being in a veritable "cul de sac," these hopes are not likely soon to be realized. It is said that many of the mines average about forty ounces silver per ton, but as the superintendent of the Madnegada mines said to me, "It costs us \$30 a ton (Mex.) to place our ore in Culiacan, and then it is nowhere," it can readily be seen that forty-ounce ore is not good enough.

There are two mills in the camp, about 1000 feet below the town, on the creek, run by water power. The hand-sorted ore and concentrates are shipped and the remainder lixiviated, with more or less success.

We arrived in Topia just before noon, and as I was informed that the creek in the canyon below was impassable, we stayed there until the next morning. When we arrived at the creek the next morning, after an hour's ride down a steep, but good trail, we found the water still deep, though it had fallen 6 inches during the night. We crossed the first half dozen fords without a mishap; but after that we began to find pack trains camped all along the trail, and as we neared where the water and trail ran through a narrow, deep gulch we found packs of all kinds piled on each side of the trail, telling of woe to the packers the day before.

Where the trail goes down the gulch for 50 yards it is not over 20 feet wide, the trail following a narrow, smooth rock ledge on the side, then running down the center, along a ridge worn smooth and slick by ages of polishing, it then crosses back to the edge. This was covered for the whole distance with about a foot of water, while at the side was a seething whirlpool 8 feet deep. And we had to ride down that trail. When I came to the place where the trail enters the water my mule refused to travel, and when I remonstrated with the spurs she returned the compliment by kicking one of the stirrups off my foot. Finally we started, and I guess we both held our breath; I did any way, for at every step I expected we would slip, and that meant a swim. All three of us—myself, the mozo and the pack mule—passed in safety here, but we were not to escape.

Two and a half hours ride farther down the canyon another stream joined ours, and then the real fun began. Almost every ford was deep enough to reach the saddle, but as we were going with the current we were really pushed across. About 11 A. M. our pack mule lost her footing, and for a moment was lost to sight. As she fell up stream the current aided her to her feet, but everything was wet through. A little farther on the stream ran through a narrow gorge, with perpendicular walls on each side. The only apparent route was along one wall and for a few yards we went all right, but suddenly it deepened, and the next I knew we were swimming. I immediately turned the mule's head for the opposite side, and after rushing along for 20 feet (all in a second) we struck high ground again, but I was wet to above the waist. The pack had another soaking. After I had emptied the water out of my saddle bags we resumed the march. About 1 P. M. we arrived at some houses where we bought fodder, and about half a mile below went into camp. Everything was spread to dry and in two hours we were ready for the road again.

I noticed several times that we had companions in hard luck. At one crossing a poor burro lay. He had fallen and before help could reach him had drowned, as the pack held him down. Another mule—of a train we met—loaded with sugar, had fallen, with the result that syrup was oozing from every crack of the boxes.

Just at dusk we arrived at a little ranch and stayed for the night. We secured corn and fodder for the mules, and by buying a plate of hashed beef at one house and tortillas at another, my mozo and I made a fair meal without drawing on our own supplies. One is struck by the number of ranches along the canyon; every patch of even one-quarter acre is cultivated. We had traveled nine hours and forty minutes that day and in eight and one-half hours had crossed the stream 92 times.

The next morning, bright and early, we were

under way, and by 11 A. M. reached Aguacaliente, the point where the canyon enters and the trail leaves the river. We had crossed the stream 59 times during the morning, making 151 times in all.

That night we reached Milpas, where man and beast fed well, and the next day, April 6, crossed the stream, now the Tamazula river, for the 153d time, and at 1 P. M. reached Culiacan, our destination.

## Concentration of Zinc Ores.

The following interesting description of the concentration of zinc ores at Kaslo, B. C., is from the Kaslo Daily News:

The zinc plant, built by the Kootenay Ore Co. at Kaslo the past fall and winter, is completed and in operation. The building, 80x75 feet, adjoins the company's sampling plant, and is so situated on the banks of Kaslo bay that the ore is received from railroad cars at the top and delivered to the steamers beneath by gravity.

The ore is received in large bins below the level of the track, from which it is fed by automatic feeder to the roasting furnace, of the White-Howell revolving type, with a capacity of 60 tons per 24 hours and upwards, according to the amount of roasting required. After being roasted the ore is cooled by passing through an iron revolving chamber, where it is rotated through currents of cooled air, and thence, after a preliminary sizing and recrushing of the oversize, the ore is elevated to the top of the building, where it is subjected to close classification, eight bins being provided (with accommodation for more if necessary), to contain the various degrees of fineness, each accurately sized. The ore is now ready to be delivered by an automatic feeder to the process of magnetic separation, whence the finished product proceeds directly to the shipping bins.

The plant is working smoothly, and the results so far obtained have been very satisfactory, the product ranging from 50% to 55% zinc, with a minimum of iron. As the success of this process depends largely upon close tests and experiments of the action of every separate grade and class of ore during every stage of the process, there will be no haste used in pressing the output during the next few weeks, an interval which is being used by the mines in starting up their concentrating plant after the winter rest.

The plant has been designed throughout on liberal lines as to capacity and space; there is room for any additional amount of bin accommodation, and for the addition of any number of other magnetic machines which may be found necessary as the business increases. As the process of development in the mines may reveal zinc ores of a more complex and difficult character than has occurred so far, requiring a special type of machine for dealing with each variety, ample space has been allowed for any such additions in future without the delays involved by alterations of the building or foundations.

The broad effect of a custom plant of this character being in operation at a point accessible to the zinc-producing mines of the Slokan district will be that the vast bulk of ores containing zinc hitherto occurring in the mining of silver-lead can be saved and shipped as an important addition to the profits of the mine, instead of being sorted out at considerable expense and thrown away, as has hitherto been the case. The importance of this factor in the mining, as well as in the transportation, business of the district is very great. In many mines the occurrence of a body of zincy material has put a stop to further development. Now the actual work of development can be made profitable with a market offering for the zinc material, in addition to which the opening up of new bodies of lead ore must inevitably follow the working of the intervening zinc belts.

In mines which have concentrating mills it has been found difficult by wet concentrating to make a payable zinc product, which must exceed 37% zinc, a point at which it does not pay to ship. The magnetic process, by raising the grade of the zinc concentrates 50%, makes the product salable at a good profit. Many mines which have no mill contain bodies of zinc ore worthless as they stand, but which, by magnetic separation, can equally be made salable.

To the transportation companies no less than to the mines the marketing of this immense additional tonnage may represent an asset of great value; but it must be remembered that the comparatively narrow margin of profit in dealing with zinc ores absolutely demands that they shall be handled at the lowest possible cost, and therefore on a fairly large scale. In order to realize from this district the full benefits which the zinc business offers, it is imperative that the transportation companies should do their share in opening up this new source of revenue. Facilities for the cheap handling of these ores in bulk, as well as transportation rates which make it possible for business to live at the start, will amply repay the transportation companies in the tonnage which can be built up; but it is essential that aid in this direction should be forthcoming at this stage. The mines have done what they can in remodeling the equipment of their mills so as to save the zinc instead of treating it as waste; and now the Kootenay Ore Co. has provided in its custom plant for zinc separation at Kaslo the further link that was needed to turn out a marketable product.

## The Rational Design of Head Frames for Mines.

Written for the MINING AND SCIENTIFIC PRESS by  
GEO. S. BINCKLEY.

In an article published some years ago in the MINING AND SCIENTIFIC PRESS the writer called attention to the very bad design generally exhibited in the head frames used, not alone in the cruder and more remote mining districts, but in those farthest advanced along other lines of development and equipment. Those remarks and the illustrations that accompanied them were not intended as a criticism alone, but to indicate a line along which improvement might be made, and attention was called then to the nature and direction of the strains that are to be resisted by such structures, and the almost total disregard shown such facts in the great majority of head frames then in use.

So long as the structure under consideration was a crude wooden affair this state of affairs was not so surprising, but when the design was made under the direction of the engineers of some responsible concern engaged in structural steel work it was to be expected that a different class of structure would be developed. In many cases, however, especially in Australia and South Africa, the steel was merely substituted for wood, and the old style was adhered to. The result of this carelessness has been the construction of some steel head frames that are, to say the least, astonishing when the nature of the strains which they are expected to resist is considered, and illustrate a wasteful use of material that would not be countenanced for an instant in a roof truss or bridge.

The writer had, about the time of the publication of the article referred to, completed the designs and seen the successful construction of four very heavy steel head frames in Butte, Mont., these frames being erected on the High Ore, Mountain View, Leonard and Diamond shafts of the Anaconda and Boston & Montana companies.

The principle of the design of the head frames referred to was based on the fact that the pyramid is the form of maximum stability. The sheaves were so placed that the working strains were transmitted, with a very small amount of eccentricity, directly to the foundations under the four main corner posts, and in actual service these structures proved to be all that could be desired in stability, although two of them, having a height of 100 feet to the center of the sheaves, had a relatively small base. The accompanying engraving of the High Ore frame at Butte, Mont., is one of those in question.

Steel Head Frame of Four Post Type.

Radically as these structures departed from the form common at that time, further study and investigation indicated that a much greater degree of economy of material and superior stability could be attained by a modification of the principles of design,

and the writer now offers for the consideration of mining engineers a design for head frames which he believes to represent in its principles the minimum expenditure of material for a certain factor of safety, combined with the maximum of stability under service conditions and greatest convenience in handling ropes, cages and skips.

This design, shown in Figs. 1 and 2, is as consistently applicable to wooden structures as to steel, and while the value of the material involved might not be as important in the former case, the superior rigidity to be attained is of great importance.

The principle on which this design is based is the transmission of the working strains on the sheaves directly to the foundations, in a straight line, and without the introduction of working strains in the bracing system of the structure. This end is attained by placing the sheave bearings directly on the ends of the two main inclined back columns, which, spread well apart at the base, are brought close together at the top. The inside bearings of the sheaves (in case more than one is used) are carried by a short beam of such depth and stiffness as to preclude the

Fig. 1.

Fig. 2.

possibility of even the slightest deflection under load, this beam being carried in turn by the hack columns and made as thoroughly an integral part of these columns as possible.

The back panel of the head frame, consisting of the two main inclined columns, the connecting beam at the head, and the lateral bracing system arranged in as many subdivisions as are demanded by the dimensions of the structure, forms the principal compression member, and through it, in fact, practically all working strains are transmitted to the foundation direct, as this back panel, considered as a single compression member, is placed near the line of the mean resultant of the working strains on the ropes, its actual position being always a little outside this line, toward the hoist.

If the panel is properly proportioned for the loads to be carried, and each back column designed to resist the compressive strains that it will be subjected to in practice, with whatever factor of safety is considered desirable, all the rest of the structure may be relatively very light indeed, as the purpose of stability may be served by a bracing system of such strength only as to resist that part of the weight of the back panel, sheaves and platform due to the inclined position of the back of the frame. The guide posts (which, by the way, the writer strongly recommends be timber in any case), serving as a support for the guides for cages or skips, may be bolted to suitable struts as indicated in the figures, and will not call for very heavy support, as there are no lateral strains on the guides where self-dumping skips are not used, and even in this case the strains, if intelligently resisted, are not necessarily at all serious in their nature.

The writer first developed the principles of this design in the early part of 1899, and as a matter of fact foreshadowed its publication at the time the previous article on steel head frames was written. (See MINING AND SCIENTIFIC PRESS, July 22, 1899.) No attempt has been nor will be made, on the part of the writer, to take out a design patent covering the principle of the head frame illustrated, but in this connection attention is called to the fact that a patent was issued a year or so ago to a German engineer, on a head frame embodying the same principles. However, as the writer's own sketches and designs based on this principle have been freely shown and used for a number of years, the value of the German patent would appear to be nil.

The economy of material in the design of a head frame, where the principles laid down are observed, may easily exceed 30% in the case of a steel frame as compared with one designed on conventional lines, and this may be exceeded where wood is the material used, as that part of the structure supporting dead weight alone or serving the purposes of stability may be relatively very light and may safely be spiked together instead of bolted.

One final remark is ventured. In no case should the heads of the columns be farther apart than necessary, and on no account should the posts be vertical, except those in front, as shown in the side elevation of the frame (Fig. 2). Only by the retention of the pyramidal form of the structure as a whole can it be mathematically consistent and actually stable. So long, however, as the principles illustrated are not departed from, and intelligent care is used in the proportioning of the main members of the structure, practical results of a highly

satisfactory nature may be anticipated with confidence, both as regards low first cost and satisfactory service under working conditions.

### Rapid-Economy Stamp Mill.

Less than two years ago G. C. Richards of Oakland and San Francisco, Cal., produced his "camless" mill—"Richards' rapid-economy stamp mill"—the fruit of

as with any mill, but the shoes and dies have to be renewed more frequently on account of the greater amount of crushing they are designed to do. The recoil of the blow is taken up by the locomotive steel springs on the stamp stems. These springs are also designed to defer the crystallization of the stamp stems to a great extent; but, in case a stem does break because of crystallization, it is reversible."

The present type of this mill is a battery of three (and multiples of three) 800-pound stamps with 8-inch shoes and dies. The manufacturers say that these stamps crush six to eight tons to the stamp through a 40-mesh screen in twenty-four hours with but 4 H. P. to each stamp.

These mills are being built by the Rapid-Economy Stamp Mill Co. of San Francisco, Cal., with head offices at 601-2-3 Examiner Bldg. of that city.

### THE PROSPECTOR.

The ore from Elk City, Idaho, is illmenite, also called menaccanite (titanic iron), in what appears to be a pegmatitic granite.

The two rock specimens—No. 1, white, flat and streaked with violet colors, and No. 2, speckled with small dark red spots—are tuffs. In their present condition they may be called claystone.

The ore from Battle Mountain, Nev., is dense siliceous rock, probably an altered felsite or other intrusive rock, containing a considerable amount of arsenical iron sulphide. The yellowish green stains are the result of the decomposition of this mineral.

The rock specimen from Sonoma, Cal., is a typical trachyte. It contains abundant phenocrysts of sanadine (glossy feldspar), the characteristic feldspar of trachytic rocks. Ore deposits and mineral veins sometimes occur in rocks of this description.

The rock specimen from Cedar Creek, Idaho, marked No. 1 is hydro-mica schist, in which there have been developed innumerable very small crystals of tourmaline. The rock may be called, then, "mica-tourmaline schist." A small amount of graphite is also present.

The mineral from Pearce, Ariz., is a combination of lead and antimony, probably zinkenite. The composition of zinkenite is sulphur 22.3, antimony 41.8, lead 35.9. Arsenic sometimes replaces part of the antimony. The ore contains no molybdenum. There is no zinc in zinkenite, and there are several minerals which closely resemble it. Among these are andorite, jamesonite and dufrénoyite. These minerals all differ slightly, chiefly in crystallization, but have about the same color, streak, specific gravity, and approximately the same composition.

The mineral specimen from Carson City, Nev., marked F. A. M. is tourmaline, a silicate of iron, magnesia and manganese, with several other elements. The composition of tourmaline is variable. This variety (the black) has no value. Pink, green and some other colored tourmalines, when transparent and without flaw, are valuable as gems, and are used for that purpose. Gem tourmalines are found in at least three localities in California, viz., Pala, Hemet valley and Mesa Grande, in the southern part of the State.

The rock specimens from Hood River, Or., are: No. 1, a much altered eruptive rock, in which there is considerable green iron silicate. No. 2, amygdaloidal lava, with considerable iron silicate, with some zeolites. No. 3, also a green-stained fragment of lava. The white rock in No. 3 is chalcedony, a form of silica deposited from solution in a cavity. No. 4 is andesite, in which are numerous crystals of a translucent mineral showing brilliant "schillerization"—that is, a bright play of colors, green, golden and blue. This mineral is olivine. Nos. 5 and 6 are sands containing a large amount of magnetite. No. 7 is basaltic lava. The white in No. 7 package is semi-pal. No. 8 is basalt.

### Deep Mining in Victoria.

The Town and Country Journal gives the following brief description of the latest operations at the New Chum Railway mine, Bendigo, Victoria, the deepest mine in Australia: "Gold has been seen in the center-country winze, below the 3856-foot east cross-cut at the New Chum Railway, which has a total depth of 4152 feet. This winze has now traversed stone on the east side for a distance of 12 feet, and the bottom of the winze is going down, all in quartz. It would appear that the winze has been sunk through a neck of stone, and that operations are now proceeding in the cap of a formation. In the bottom of the winze on the east side the stone, which higher up was very white, is improving in appearance and is now of a streaky character, and shows a little mundic. Only one color of gold has as yet been seen in the deep winze, but it is unique as being the deepest gold found in the southern hemisphere."

Head Frame High Ore Mine, Butte, Mont.

many years' labor and observation, which, it is claimed, is founded on the principle of leverage. In place of the cam is substituted a lever with a purchase of 4 to 1, which intent is to operate the Richards' mill with one-half the power required by a gravity mill. The levers are actuated by a crank shaft revolving with sufficient rapidity to cause the stamps to strike 200 to 250 blows per minute. By this combination it is claimed that 1 H. P. suffices for each stamp.

Mr. Richards asserts: "My mill bears the same resemblance to the cam mill that the latest style automobile does to the early stage coach. The good old stage was all right for its time; but it was slow, uncertain and expensive. The cam mill does only half the work with twice the power required by my mill—and with my mill there are no doubtful results. Those heavy, hammer blows, striking at such a high rate of speed, crush anything in the way of ore, no matter how hard it is."

This mill has individual mortars (Mr. Richards' patent), are circular in shape, each mortar having a screen surface of 480 square inches, making a total

Rapid-Economy Stamp Mill.

of 1440 square inches to a battery of three stamps. Each stamp, besides having its individual mortar, has its own automatic feeder and water supply.

"The screens wear evenly and last about as long

## Examination and Valuation of Mines.\*

No. IV—CONCLUDED.

**WEIGHT OF SAMPLE.**—The weight of the sample broken down will vary with the width and hardness of the ore. When it is larger than the capacity of the sample bag, the sheet must be carried to a convenient place underground and its contents broken down to the size of a walnut. When this has been done, the sample is thoroughly mixed, formed into a very flat truncated cone and quartered.

Two opposite quarters are rejected, being removed completely with all their fines from the sheet. The material in the two remaining quarters is then broken down to a size half the diameter of a walnut, thoroughly mixed, and again quartered. The two quarters lying in the position of the two quarters retained in the first operation are rejected and removed from the sheet.

A common method of mixing the ore on the sampling sheet is to toss the material from one side to the other. In this process care must be taken to insure that the fines are not concentrated in one particular part of the sample, but evenly distributed throughout the whole mass before each quartering.

In three quarterings, a sample weighing eighty pounds will thus be cut down to ten pounds, which is about the maximum capacity of your sample bags.

The time required to break down a sample will depend upon the hardness and size of the lode. It seldom is less than half an hour, and may extend to several hours, depending upon the number of quarterings needed to reduce the sample to a convenient weight. The sampling of a large mine may occupy several weeks and run into a cost of several hundred pounds.

**ASSAY OF SAMPLES.**—The whole of the sample should be dried, crushed in a rock breaker in the laboratory to pass through a 10-mesh sieve, mixed and sampled by quartering till reduced to a pound or two in weight, all of which should be finely pulverized, passed through a 60-mesh sieve, again mixed, and divided into two portions. One portion is handed to the assayer, while the other is retained as a duplicate sample for subsequent reference and verification if the necessity should arise.

Carelessness in the laboratory may stultify all the care exercised in the sampling underground.

If the mine examiner submit his samples to an assayer whose qualifications are unknown to him, he should take care to be present during the crushing, pulverizing and final division of the assay samples.

The duplicate samples should be put into small calico or stout brown paper bags, labelled and secured in a lock-up sack, which should be removed from the laboratory.

The examiner's samples should never be submitted to the mine assayer; and only in very exceptional circumstances should the samples be placed in the hands of an unknown assayer.

**CALCULATING AVERAGE WIDTH AND VALUE OF VEIN.**—The assay values may be expressed in pennyweights of gold per ton; percentage of metal; or, in the case of low-valued gold or bullion, the money value may be stated in dollars, or pounds, shillings and pence per ton.

The thickness of the ore is most conveniently expressed in inches for veins up to 8 or 10 feet thick. Take the case of ten samples from a gold-bearing vein as follows:

No. of Samples.	Width of Vein in Inches.	Assay Value Per Ton in Pennyweights.	Inch—dwt.
1	40	8	320
2	36	9	324
3	32	7	224
4	34	5	170
5	28	9	252
6	30	6	180
7	34	8	272
8	38	5	190
9	40	7	280
10	44	4	176
Totals	356		2,388

The average width is found by dividing the sum of the widths by the number of samples. Thus in this case we have  $\frac{356}{10} = 35.6$  inches average width.

The average assay value is found by dividing the sum of the inches-dwt. by the sum of the widths as under:  $\frac{2,388}{356} = 6.69$  dwt. per ton for a width of 35.6 inches.

**EXCEPTIONAL ASSAY VALUES.**—A sample giving an exceptional assay value may be dealt with in different ways. It may be discarded entirely and not included in the average; or ascertain the average value with it included, and replace the original exceptional value by this average, and then calculate the average value for the average width.

For example: Five samples gave values of 10 dwt., 20 dwt., 25 dwt., 120 dwt. and 25 dwt. per ton. The average is 40 dwt. Replace the exceptional value, 120 dwt., by 40 dwt., and then proceed with the calculation of results.

The exception value may represent a small patch of rich ore, or a bunch of rich ore increasing in dimensions going upwards or downwards, or even a solitary speck of gold. The most satisfactory manner of

dealing with an exceptionally rich assay from a sample is to resample the vein a second time.

**FUTURE PROSPECTS.**—When satisfactory values have been obtained around a block of ground, the natural inference is that the area of ore is of the same approximate value. Experience has shown that where a block is exposed in four dimensions such inference is fair and reasonable. Where the block is exposed in three dimensions the inference may be open to some doubt.

Before arriving at a definite conclusion as to the future prospects of the mine it is advisable for the examiner or mining engineer to carefully consider the following questions: (a.) Is there any change of rock formation enclosing the lode in any part of the mine? If so, what influence does this change of country exercise upon the value of the ore? (b.) Is there any indications of barren zones of ore, either in depth or horizontal extension, along the course of the lode? (c.) Are the values in the zone of oxidation likely to be maintained in the unoxidized portion? (d.) What are the probabilities of impoverishment in depth?

**SAMPLE VALUES AND MILL RETURNS.**—Manifestly the assay values obtained represent only the values of the actual material broken by the examiner. The variations of value obtained at the different intervals clearly emphasize the variable value of the ore. Hence the mean values deduced from the assay values can only be regarded, even in the most favorable cases, as close approximations.

A mining engineer with a personal knowledge of the ore and values in a mine extending over a considerable period can often so adjust his averages by the experience of the past as to make a very close estimate of the quantity and value of ore in newly developed ground in the same or adjoining mines.

The discrepancy that often exists between the sampler's estimate and the mill returns, in the case of gold ores particularly, may be due to one or several causes, among which the following may be enumerated: (a.) A sudden increase of width of ore without a corresponding increase of values. (b.) A sudden decrease in values, or the payshoot may split into two legs and reunite between two levels. (c.) A greater proportion of mullock or rock is sent to the mill than was contained in the examiner's samples. This is a contingency very liable to occur in the breaking of a narrow vein in the stopes, especially where the vein is less in width than the width of the breast or face. In cases where the walls of the vein are well defined and the stripping easy, the proportion of rock introduced with the ore is not likely to be very great, especially where a stretch of ore is stripped before it is broken. (d.) Imperfect tally of the tonnage of ore sent to the mill. (e.) Inadequate allowance for moisture.

The sampling of a mine for valuation purposes is most exhausting, both physically and mentally. When the work has been carried out carefully and conscientiously the mine examiner should be prepared to stand by his results.

The examiner must remember that he is the confidential adviser of his principals, and for that reason must keep a discreet silence about the results of his examination, and of his opinion as to the probable value of the mine.

**SAMPLING OF DUMPS OR PADDOCKS OF ORE.**—The stack of ore is divided into a number of small blocks by two systems of cuts or trenches passing through the ore at right angles to each other.

(a.) Each block can now be sampled separately by picking pieces of ore from its four sides.

(b.) Or the material excavated from the trenches can be wheeled to a clean piece of ground, spawled into small pieces, mixed, and quartered repeatedly until a sample of convenient size is obtained. Before each quartering the larger pieces of ore must be broken to half their diameter in the preceding quartering.

(c.) Or the material from the trenches can be crushed in a rock breaker, mixed, and quartered down till the assay sample is obtained.

**SAMPLING HEAPS OF TAILINGS.**—If the accumulation of tailings is large it should be sampled in separate sections, as large piles of sands are liable to vary considerably in value in different parts.

Stake off the heap, so as to divide it into sections about 5 yards square. Make a diagram in field book corresponding to sections. Record the dimensions of the sections, and distinguish each section by a letter, as A, B, C, etc.

Sample each section, beginning with section A: (a.) With a sampling iron take samples all over the section at, say, every foot or two. (b.) If there is reason to believe that the values are not the same from top to bottom, put the top material into one bag and the lower into another; or, if necessary, separate samples can be taken for every foot of depth. (c.) If there is no sampling iron available, holes are dug at intervals of every 4 feet or 6 feet. The sands from the holes are wheeled to a clean place, mixed, and reduced by quartering to a convenient size.

If required, the sand obtained from different depths can be kept separate.

**SALTING OF MINES.**—By "salting" is meant the illegal enrichment of the ore, with the object of giving the property a fictitious value. The mine ex-

aminer should be familiar with the methods adopted by unscrupulous persons, so as to be able to protect the interests of his principals.

A common method is to tamper with the examiner's samples; and for this reason the samples should always be in safe custody until the assay samples are known.

Cases are known where the sample bags have been enriched before the samples were put into them. It is therefore a wise precaution to keep the sample bags in a lock-up sack until they are required. And even then it is advisable to turn each bag inside out and shake vigorously before use.

In the case of gold mines soft ore has been artificially enriched to a depth of a foot or more with a strong solution of chloride of gold. Fraud has been practiced on mine examiners by stretches of rich ore having been skillfully built into the wall of a level at different intervals and at the working face, the joints being obscured by liberal splashes of mud. In the same way artificial outcrops have been prepared.

Dumps of ore have been stacked with rich ore on the sides and top surface. An imposture of this kind is at once disclosed by the process of trenching when procuring samples for assay.

Samples of gold wash intended for examination by panning have been enriched, either before or during the washing, by the agency of gold-bearing tobacco ash, pellets of clay and gold-bearing finger nails. The gold obtained from the panning of gold wash or tailings should be examined under the microscope.

Bulk samples of ore have been salted during the process of treatment in the battery, either by the addition of gold or amalgam.

The examiner's samples may be unlawfully enriched at any stage from the breaking of the material in the mine to the assaying in the laboratory. Strong solutions of gold chloride have been injected into the bags with a syringe and gold dust added to the litharge and fluxes. Fraud is so easily practiced in this stage that the examiner should either supply his own assay materials or test those placed at his disposal.

In these days of mine valuation by systematic sampling, cases of stacking or salting of the ore in the mine are rare, and easily circumvented by the watchful examiner. But, besides covert acts intended to beguile, the examiner may be misled by the suppression of important developments, or by the blocking up of workings where unfavorable results might be obtained.

On his part the mine examiner must take care not to assume an attitude of restraint and distrust towards those connected with the management. In the writer's experience, miners are as honest as most men; and if they sometimes put the best side before you it is more from a feeling of loyalty to their employers than a deliberate desire to deceive. Probably not more than one in a hundred would willfully mislead you, or use unlawful means to enrich your samples. But the hundredth man is generally a clever rogue and needs very close watching; and because of this one man you must take no risks, either in the mine or in the laboratory.

## Duty and Authority of Forest Rangers.

The following communication was received some weeks since from a claim owner in Fresno county, Cal.:

TO THE EDITOR:—I own four placer claims in the Forest Reserve and am working them nine months out of the twelve each year. My assessment work affidavit is on record for last year in Fresno. I make one report to the United States Mint and one to Charles G. Yale yearly. Now a Government ranger comes along and wants me to give him a report of how much my mines have produced, and further says if I don't give him the report he will put me out of the reserve. I shall not give him any such report, and I wish you would kindly inform me through "Concentrates" if there is any law to compel me to give it. I always consider what you say final.

Toll House, Cal., May 18.

This matter was referred to the Commissioner of the General Land Office at Washington, D. C., in the belief that possibly some new regulations had been issued which gave forest rangers the authority the above communication would suggest they had in such matters. Following is the reply of the Acting Forester:

TO THE EDITOR:—I have received your letter of May 11, 1905, by reference from the Commissioner of the General Land Office.

The forest ranger you refer to was doubtless making his proper official inquiry in regard to the character of the mining claims and the compliance with the law by the applicants. The forest ranger has no authority to threaten a person or to put him off the reserve for refusing to give information. He has no authority to remove a claim holder from a reserve without due process of law; but the law gives him authority to make arrests for the violation of the laws and regulations relating to the forest reserves and national parks. A miner, acting properly, is as secure in his mineral possessions in a forest reserve as though he were on any other portion of the public domain.

No recent regulations have been issued concerning mining in forest reserves.

OVERTON W. PRICE,  
Washington, D. C., May 25. Acting Forester.

\* Prof. Jas. Parks in N. Z. Mines Record.

# Spitzluten.\*

Written by H. LEUPOLD.

During the discussion on Mr. H. S. Denny's paper in October, 1903, I criticised in passing the spitzluten in general use on the Rand, and some of my friends have since been inquiring whether I had anything better to offer.

As the subject is attracting a good deal of attention in connection with tube mills, I think the following description of a spitzlute I made for the Treasury and now in use there in triplicate since July last may prove interesting.

As shown by Figs. I to V, this is a modification of

Fig 1

Fig 2

Fig 3

Fig 4

Fig 5

the Bilharz spitzlute, but built of redwood, as cast iron is easily worn by coarse sand under water. The wood is treated with boiling linseed oil until it will take up no more. The foundation consists of three solid blocks, a, b, c, each 3 feet 3 inches long, in which the channels and slots required are easily cut. These blocks, when assembled on white lead joints and bolted together, form a single block 11 inches by 11½ inches by 3 feet 3 inches. The main vertical slot is 2 feet 3 inches long and ¾ inch wide, being protected at the upper entrance by two ¼-inch steel plates, p, p, bent to the required angle and simply screwed on from above. This slot widens downward to 2 inches and there forms the channel d, sloping to the discharge orifice. A 2-inch pipe, 3 inches long, of which one-half is cut off lengthwise for 2 feet 3 inches, as shown, forms the bottom of the channel d, and also

the discharge end e, which protrudes slightly. It is threaded for screwing on a flange and the coupling to gooseneck. The coupling should be a T with wooden plug for sluicing out. The clear water is admitted through a 2-inch pipe and cock, g, into a square chamber, h, from where it passes through a horizontal slot, i, ¼ inch wide and running the whole length of 2 feet 3 inches into the vertical slot and chamber, d. Another small chamber, k, receives clear water through a 1-inch pipe and cock for flushing out purposes. The baffles consist of single ¼-inch steel plates, l, l, running in grooves formed by screwing 1-inch by ¼-inch slats to the vertical sides of the spitzlute. There are several of such grooves, and a little iron cleat prevents the plates from dropping too far. The chamber, h, is closed on the outside by a 1½-inch plank screwed on, and to this the cock flange is screwed in its turn. The main vertical slot being ¾ inch by 2 feet 3 inches, offers an area of over 10 square inches, and this would require a stream of clear water far greater than desirable. In the Bilharz spitzlute such slot is ¼ inch wide, with parallel sides, and invariably chokes up in a short time by coarse gravel lodging in it. To reduce the area of this slot in my spitzlute, I block it with seven wooden wedges 3 inches by 4 inches by ¾ inch to 1 inch thick, spaced ¾ inch apart, thus forming eight discharge slots ¾ inch by ¼ inch, having a total area of only 2 square inches.

The concentrates are guided to these openings by seven small wooden tetrahedrons, n, having their lower edge truncated or flattened ¼ inch and nailed in position. The sides of these tetrahedrons are about 3½ inches long.

The purpose of the two inclined side planes of the central hole spitzlute is thus attained, but whereas in the latter these form a single inverted pyramid bottom of great depth, causing strong eddies and rendering close classification impossible, the eight small funnels, only 3 inches deep, do not interfere with the regular flow of the pulp stream over the whole width of the spitzlute, and perfect classification is obtained.

I will conclude by giving results obtained from an average of many samples, both of concentrates and overflow.

Passed through mesh per lineal inch.	Remained on mesh per lineal inch.	CONCENTRATES.			OVERFLOW.		
		%	dwt. per ton.	Gold Value %	%	dwt. per ton.	Gold Value %
17	40	63.67	6.22	43.41	6.31	4.3	5.49
40	60	28.81	12.60	39.79	10.41	4.5	9.48
60	80				5.03	4.83	4.93
80		7.52	20.42	16.80	78.25	5.06	80.10

It will be seen that the concentrates consist of 63% coarse sand of low value, a middling product, and of 7½% fine pyrites of over 20 dwts. There is no slime, and the water is quite clear. The overflow contains only fine sand of 4½ dwts., and all the slime.

There are four separate means of regulating the work of this spitzlute—

1. Altering the width of main stream by changing baffle plates, l, l, in the various grooves.
2. Varying admission of clear water at g.
3. Varying admission of clear water at k.
4. Raising or lowering gooseneck discharges which pivot around the T couplings at e.

I find that a head of water of 9 inches is sufficient on the discharge orifice, by which a head of over 3 feet is gained, as against the ordinary spitzluten, where the discharge is below, and controlled by an ordinary throttling cock. The construction described can easily be adapted to a sands and slimes separator, where but little, if any, clear pressure water would be required, and the advantage of saving 3 feet in the diameter of a large tailings wheel is too obvious to require insisting on.

## Production of Talc and Soapstone.

The total production of talc and soapstone of all varieties during 1904 was 91,189 short tons, valued at \$940,731. As compared with 86,901 short tons, valued at \$840,060 in 1903, this is an increase of 4288 tons in quantity and of \$100,671 in value, due partly to a general increase in the production of talc from all States, but principally to the large increase in the production of fibrous talc in New York. In 1903 there had been a large decrease in the production of fibrous talc in New York as compared with the production of 1902, which was due to long-protracted strikes at some of the paper mills.

Of the 1904 production, 27,184 short tons, valued at \$433,331, were obtained from all the States exclusive of New York. This value includes that of the manufactured product made from the talc, as only a small quantity of the product is sold in the crude state. The production came from nine States, and these, together with the number of producers in each, were as follows: California, 1; Georgia, 2; Massachusetts, 1; New Jersey, 1; North Carolina, 5; Pennsylvania, 2; Vermont, 3; Virginia, 2; Washington, 1—a total of eighteen producers.

## Personal.

F. A. DE COSTA of Goldfield, Nev., has been in San Francisco.

CHAS. COLCORD has charge of the Willey mill at Kokomo, Colo.

CHAS. TAYLOR has charge El Oro Co.'s mines at Poza, Sonora, Mexico.

JAS. KLEGG is manager San Martin mine at Uruachic, Chihuahua, Mexico.

J. C. WAGGONER is general manager H.-Y. mine, near Roosevelt, Idaho.

H. R. KING, of Grand Rapids, Minn., is examining mines near Placerville, Cal.

C. J. BAKER of Davenport, Ia., has been examining mines, near Rochford, S. D.

T. B. CROW is metallurgical engineer Colorado-Oregon M. Co., at Bohemia, Oregon.

D. DRISCOLL is superintendent Keane Wonder Extension M. Co., near Ballarat, Cal.

BENJ. MARTIN has been appointed superintendent Beta mine at Iron River, Mich.

J. W. NEILL has retired from the superintendency of the Heinze mines in Butte, Montana.

C. M. FUELLER, of Denver, Colo., has charge of work on the Northrop mill, at Silver Cliff, Colo.

A. HOSKINS, of Silver Cliff, Colo., is in New York City financing his mining properties.

H. C. GRIGSBY has gone to Nome, Alaska, to become assistant superintendent Ophir mine.

E. A. JULIAN has been appointed superintendent mill at Florissant, Teller county, Colo.

L. W. SHINN has resigned as superintendent Utica mine at Angels, Calaveras county, Cal.

F. W. DENTON has succeeded L. L. Hubbard as manager Champion M. Co. at Painesdale, Mich.

D. S. COCHRANE, superintendent Jerome Copper Co., at Jerome, Ariz., has been in Pittsburg, Pa.

G. A. SCHROTER, a mining expert for the Venture Corporation of London, is in San Francisco.

F. W. BRADLEY of San Francisco, Cal., has been elected president Federal M. & S. Co. of Idaho.

F. G. FARISH has returned from Sonora, Mexico, and is at present examining mines at Telluride, Colo.

D. A. HERRON, superintendent Tomboy mine, has returned to Telluride, Colo., from a visit at Helena, Mont.

G. H. SAMPSON, vice-president Rand Drill Co., New York, has returned there from a trip to the Pacific coast.

A. H. BUCK of Denver, Colo., has been appointed superintendent Panuca mine, near Monclova, Coahuila, Mexico.

E. N. WALKER of Soulsbyville, Cal., has been appointed superintendent Big Conqueror mine, near Goldfield, Nev.

F. S. WILHELM has been appointed general manager Arizpe M. Co., near Cananea, Sonora, Mexico, succeeding J. P. Hallihan.

J. H. ROGERS has resigned as superintendent Velardena smelter at Torreon, Chihuahua, Mexico, and is in New York City.

D. M. RIORDAN of New York, managing director Bully Hill Copper M. & S. Co., is at the mine at De Lamar, Shasta county, Cal.

J. W. FINCH has been appointed superintendent Last Dollar mine, Cripple Creek, Colo., in place of Chas. Walden, who has resigned.

R. B. LAMB has resigned as manager Great Tower Hill mines, Leonora, Western Australia, and is returning to the United States.

W. S. HEGER has resigned as manager San Francisco office Westinghouse Electric & Mfg. Co. W. W. Briggs is present acting manager.

T. C. ARCHER of Prescott, Ariz., has been appointed superintendent Oregon Securities mine at Bohemia, Or., vice C. C. Matthews resigned.

C. G. WARE of Roubaix, S. D., has gone to Bluefields, Nicaragua, as electrical engineer for the Lone Star M. Co., of which A. G. Smith is manager.

HERMAN SCHUSSLER, chief engineer S. V. Water Co., San Francisco, Cal., has been appointed consulting engineer to the Isthmian Canal Commission.

W. G. LELAND and S. S. MOORE, vice-president and secretary Relief G. M. Co., have returned to New York City from a visit to the mines near Phoenix, Ariz.

W. H. MEAD, of Spokane, Wash., has charge of developing the Metaline M. & S. Co.'s silver-lead mines on the Pend d'Oreille river, Stevens county, Wash.

E. H. SNIFFIN, general sales manager Westinghouse Machine Co., East Pittsburg, Pa., was in Denver, Colo., the past week attending the Electric Light Convention.

C. H. CUTTING, of the Troy-Manhattan Co. at Troy, Ariz., has resigned as general manager and been promoted to assistant to the president, with headquarters in New York City.

DR. FRANKLIN R. CARPENTER, who built the Deadwood & Delaware smelter at Deadwood, S. D., has been engaged to take the management of the Tinton properties at Nigger Hill, in western Lawrence county, S. D.

\*Jour. Chem., Met. & Min. Soc., S. A.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

B. S. Revett of Denver, Colo., is at Nome putting up a \$100,000 dredger with a capacity of 300 H. P., and later he goes to Fairbanks, where he is building a 70-mile ditch that will be high enough to throw water upon every creek, into every gulch and upon every bench in the Tanana district. A. E. Murphy has charge of the work. The dredger hull at Nome will be 115 feet long, 36 feet beam and 7 feet deep, and will weigh 500 tons. It is expected to be running by September 1.

T. H. Ellis, general manager of the Windfall placer claim on Windfall creek, 15 miles northwest of Juneau, asserts that in sinking through the gravel for a hydraulic lift, the gravel that came out of the hole when washed averaged \$5 to the yard.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The shaft of the Shattuck Arizona C. Co., near Bisbee, continues in good ore. This is equipped with an 80 H. P. hoist and is down 732 feet. T. Bardon of Wisconsin is president, M. Pattison of Duluth, Minn., vice-president, A. M. Chisholm of Duluth secretary and treasurer, and L. C. Shattuck of Bisbee managing director. Their property consists of six claims south of the property of the Copper Queen. Bisbee, June 5.

#### Gila County.

E. F. Eisenhour is driving a tunnel on the Rye C. Co.'s property in the Mazatzal mountains, near Globe, to cut the main ore body at a depth of 500 to 600 feet. The tunnel is in 200 feet and will be driven 500 feet farther to cut the ledge.—The output of the Old Dominion smelter, at Globe, for May was over 3,100,000 pounds of blister copper, which is the largest production for any one month in the history of the company. The furnaces were in actual operation twenty-nine and one-half days and for twelve days of that period were operated with reduced blast, while the large blower engine was being remodeled. There was run through the furnaces 38,000 tons ore, slag and lime rock.—The Arizona Commercial Copper Co.'s new 150 H. P. hoist and compressor are in service at the Copper Hill mine, near Globe.—At the Black Hawk the shaft is down 100 feet.—It is reported that the Arizona-Colorado M. Co., working 3 miles north of Globe, intends to put in a 100-ton smelter. R. M. Force is president and J. L. Alexander of Globe resident agent.—The Globe-Boston C. Co. has bought the Mallory mines, 2 miles north of Globe.

#### Graham County.

The Shannon Copper Co. at Clifton have a contract with Wm. Damron for the delivery of sixty tons of lime rock daily from Limestone canyon. The lime rock will be used in the furnaces for fluxing purposes.—During May the Standard copper mines at Clifton shipped fourteen cars of ore. The lowest returns on the second-class ore was 15.90%, and the highest of that class 20%. Two shipments of first-class went 40% and 46.84%. This ore is coming from the lowest workings of the mine.

#### Maricopa County.

Work has been temporarily stopped at the White Gold mine, near Wickenburg, awaiting the arrival of hoisting machinery and building of a tramway. The road from Martinez has been put in good order.

#### Mohave County.

J. Brockman has leased and bonded the Azalia mines from H. E. Petet and co-owners, who will operate them on the Gold Road basis of work. The mines are 12 miles west of Mineral Park, which is 9 miles from Chloride.—The new Blue Ridge milling plant, in the San Francisco district, has begun the treatment of ore.—The Gold Road Co. at Acme is putting in a filter press at the mill. At the mine a 16-drill compressor is being put in.

The Arizona-Mexican M. & S. Co. has made a rich strike in the Twin mine, at Cerbat. The new ore body was opened up in the shaft, which is now down 70 feet and is being sunk under a 100-foot contract. The ore carries good values in gold and lead.—H. Lang is taking rich gold ore from his Tragedy mine, at Union Pass, near Kingman.—A rich gold discovery is reported from the Vanderbilt mine, at Vivian, where a 10-inch vein of ore has been found in the drift on the 175-foot level. The mine is being worked by the Cerbat Mountain M. Co., of which J. Boyle, Jr., of St. Louis, Mo., is general manager.

#### Pima County.

(Special Correspondence).—The Imperial C. Co., operating near Silver Bell, is shipping 100 tons daily to the smelter at Douglas. During the last fifteen months 12,000 feet of underground work has been done. A large boiler is put in at the old Union shaft, preparatory to starting work through this opening. A 10-ton experimental concentrating plant will be put up at once and the necessary machinery to permit of the use of crude oil fuel in place of coal will also be added.—The Gould C. M. Co. has nineteen claims on the northwest slope of the Tucson mountains, 15 miles from Tucson. S. H. Gould is president and W. H. Dailey secretary. The Gould property is developed by 400 feet of work, one shaft being sunk 120 feet. A 15 H. P. gasoline engine is in use and a compressor will be put in soon. Tucson, June 5.

#### Pinal County.

The Mineral Hill Con. M. Co., with mines in the Xavier district, has blown in its furnace and is shipping matte to the Copper Queen Co. at Douglas. A steam hoist and four whims are taking ores from five shafts of the mines. Another furnace is soon to be blown in, and another is to follow later.—In the Mineral Creek district the Big Lead M. & S. Co. is making a test run of

500 tons of copper ore in the Bob Tail mill, which the company has leased. It has also ordered a 100-ton concentrating plant, and expects to buy the mill and begin active operation soon.

Manager Sharpe of the Arizona Pacific M. Co. reports that he has the mines unwatered at Wooley and sinking the shaft has been resumed.—The Memania claims, between Ray and Kelvin, have been bonded to St. Louis men, who will develop them.

#### Santa Cruz County.

The Arizona Development Co. is preparing to work properties near Harshaw.—The Presidential mines in the Santa Rita mountains are receiving new pumps preparatory to development.

#### Yavapai County.

(Special Correspondence).—The Crown King M. Co. at Crown King started in concentrating its tailings May 20 and are now milling 70 tons daily. There are over 300,000 tons on the dump. Crown King, June 5.

(Special Correspondence).—Ground will be broken July 1 for the new Val Verde smelter at Val Verde to replace the one destroyed by fire a year ago. The Arizona Smelting Co. has its engineers on the ground and its plans for the new plant are perfected. It is said that the new smelter will cost about \$1,000,000. It will be built of steel and will have a capacity of 600 tons of ore a day. Suitable laboratory, office buildings, workmen's quarters and mess rooms will be built. Val Verde, June 5.

(Special Correspondence).—The recent cave-in at Jerome is less serious than at first thought. The United Verde resumed operations almost immediately. They plan improvements to be put in at once. The company will make a 40-foot addition to its smelter, put in another 500-ton furnace, a 50-ton crane and two converters. There will also be put in a Weiss condenser capable of condensing 3000 gallons of water from steam from engines per hour; a large cooling table, which will do away with the large flume running along the south side of the road leading to the depot; two new marine boilers, two pumps and a large blower with a capacity of 400 cubic feet per revolution, with special engines to handle it.—The management of the Copper Chief mine at Jerome has decided to retimber the property throughout, which means an expenditure of about \$30,000. This is necessary, as the timbering got in bad condition while the mine was shut down. It is reported that the control of the property has recently changed hands, and this new timbering is preliminary to the active starting and working of the property. Jerome, June 5.

The Cumberland mine at Crown King has resumed work with air drills.—E. A. Haggott, superintendent of the Blue Bell, near Prescott, says that the main shaft is down 500 feet. Drifts are to be started when the 700-foot level is reached. The White mine, on the Hasayampa, is to be equipped with a modern 20-stamp mill. The River Bend G. M. Co. has been organized in Prescott, with H. Henry president, M. Y. Henry vice-president and T. W. Baker secretary. The company owns the River Bend claims, 15 miles west of Hillsdale.

The Colonel M. Co., near Crown King, will put in a new hoist.—It is reported that work will be resumed at the Mudhole mine, near Walker.—A strike of rich ore is reported at a depth of 180 feet in the shaft of the properties of the Oro Con. Co., near Kirkland.

### CALIFORNIA.

#### Amador County.

It is reported that the Kennedy crosscut at the 2750 level has struck the main ore body. The shaft is to be sunk 200 feet deeper, making a total depth of 3000 feet.

Land along Dry creek, 2 miles northwest of Ione, is to be prospected as a possible dredging proposition. F. A. Kribs of Portland, Oregon, is interested.

#### El Dorado County.

A new shaft is to be sunk on the Rosencrans mine, near Garden Valley, which is being opened up by Geo. Nonguesser.—The Ida Mitchell mine at Placerville has been closed down.

#### Kern County.

A copy of the articles of incorporation of the Nevada & California Railway have been filed. The company is capitalized at \$15,000,000, of which amount \$457,000 has been subscribed by the five directors of the corporation as follows: W. F. Herrin, \$227,000; W. Hood, \$227,000; P. F. Dunne, \$1000; N. F. Smith, \$1000; J. L. Willcutt, \$1000. The company proposes to construct, maintain and operate a railroad, consisting of a main line 430 miles in length and a branch line of 27 miles. The main line is to commence at Hazen, on the line of the Central Pacific Railroad in Churchill county, Nev., and run thence south through the counties of Churchill, Lyon and Esmeralda in Nevada, and through the counties of Mono, Inyo and Kern, in California, to near Mojave station, on the line of the Southern Pacific. The branch lines will commence near Churchill, on the line of the Carson & Colorado Railway in Lyon county, Nev., and run west to Mound House station, Nev., on the line of the Virginia & Truckee Railroad.

#### Nevada County.

Work is being pushed on the overhead trolley electric line between the North Star mill and the Central hoist, near Grass Valley. When completed it will displace wagons hauling ore and sulphurets between the hoist, mill and cyanide plant.—N. P. Brown has organized a company to work the Austin and Wedge mines in Willow Valley, near Nevada City. H. Selson has charge of the work. A compressor, air drills and rock breaker and other machinery have been ordered and will be put in. It is intended to build a mill.—The 5-stamp mill has been started at the Kenosha mine, near Grass Valley. G. W. Root and company are working the property. Drifting is being carried on north and south, and is to be sunk to a depth of 500 feet.—In the Graniteville district, work has been commenced on the Republic mine by Wm. McLean and others, who have a bond and propose to open the property.

The old Keystone mine, near Rough and Ready, owned by J. Hackett, has been bonded to Eastern cap-

talists, who intend to develop the property, and put in a hoisting and pumping plant. It will be known hereafter as the Majestic. The shaft is down 150 feet.

#### Placer County.

A dredger has been put in at the Casb Rock mine, on the American river, near Forest Hill.—The Whiskey Diggins mine, north of Lincoln, has been sold by W. B. Hellings to San Francisco people, who intend to sink a 500-foot shaft.

#### San Bernardino County.

Rich quartz and placer gold strikes are reported from near Siding 16 of the new Salt Lake & Los Angeles Railroad near Kelso, the richest strike being 5 miles south of the railroad, near the foothills. Water and means of transportation, even burros, are lacking.

#### Shasta County.

Before the death of President P. L. Kimberley it was announced that the Balaklala Con. Copper Co. would commence work on a 1000-ton smelter at Kennett within sixty days.—R. E. Roper of San Francisco has bought in the interest of a company that he represents the Snyder and Last Chance mines, near Redding.

It is reported that the Trinity Copper Co. is to put in a large air compressor at the Shasta King mine, near Kennett.

#### Sierra County.

M. Phillips and R. B. Harper, both from San Jose, are interested in the King Consolidated quartz mine near Loganville. Arrangements are being made to build a 20-stamp mill on the property on the flat below the Marguerite mine and to be connected with the mine by an aerial tramway 1500 feet long. The South Fork will furnish the power.

#### Slaskiyo County.

A. Livingston and W. Everton, working quartz veins near Hiltz, are building a 2-stamp mill.

#### Trinity County.

The Lorenz placer mine on Dutton's creek, near Weaverville, is being worked by John, William and George Lorenz, although water is somewhat scarce. The boulders are moved by a derrick and drum worked by a waterwheel.

#### Tulare County.

The Himalaya M. Co. of New York is opening up a chrysoprase mine south of Deer Creek, near Porterville. L. Tannenbaum is the principal stockholder.

#### Tuolumne County.

(Special Correspondence).—At the Grizzly mine, 1 mile south of Carters, a new find of 10 feet of good ore has been made by running a crosscut into the footwall slates. The Grizzly was at one time a large producer.—It is intended to reopen the Dead Horse mine by extending a tunnel driven in several hundred feet on the Lady Washington, which joins the Dead Horse on the south. The water in the latter will be first tapped by means of a diamond drill. This tunnel will open the 1600 level of the Dead Horse, and will afford drainage and an inexpensive means of carrying mining to deeper levels, by using an air hoist located in the mine. It is said an arrangement will probably be made whereby any ore mined in the Dead Horse will be crushed in the Grizzly mill, a short distance from the mouth of the tunnel, but across the North Fork of Tuolumne river.—A good strike is reported in the New Albany, near Grizzly.—The Carlotta-Pennsylvania mines at Cherokee are being worked.—It is reported at Soulsbyville that Wm. Sharwood will reopen the Keltz mine, 10 miles north of Soulsbyville, near the Stanislaus river. The mine was worked in former years and was a good producer. It is the intention to continue a crosscut tunnel to the vein and drift. There are several good ore shoots known in this mine, none of which have been worked more than 50 feet below the lowest tunnel level. The new tunnel will cut several hundred feet below the old tunnel. Soulsbyville, June 6.

The cyanide plant has been started at the Arbona mine near Tuttletown.—It is reported that the Confidence mine at Confidence has been sold to L. R. Poundstone and will be worked by him.—Heavier machinery is to be put in at the Draper mine at Soulsbyville.

The 10-stamp mill on the John Royal mine is being moved to the Longfellow mine at Big Oak Flat.—L. W. Wiseman has succeeded H. L. Huston as superintendent of the Soulsby mine at Soulsbyville.—The mill at the Golden West, in the Phoenix lake district, has been started up. Wm. Floyd of Soulsbyville is in charge.

#### Yuba County.

It is reported that Mr. Spencer of San Jose will put in a hoist and start work at the Abbott mine at Rackerby.—H. C. Tate is examining the Seaboth and Davis mines at Rackerby for Eastern parties.

### COLORADO.

Judge Riner of the United States Court, in the case of the Eagle Ore Sampling Co. of Cripple Creek vs. the Telluride Reduction Co., has decided that ore shipped to a smelter or reduction plant is the property of the shipper until the consignee settles for the values obtained in the shipment. The case is, that the General Metals Co., operating at Colorado City, now in bankruptcy, succeeded to the rights of the Telluride Reduction Co. The Eagle Ore Sampling Co. had a contract for the treatment of ore. When the General Metals Co. collapsed it undertook to construe this contract as one for the sale of the ore, when, as a matter of fact, it had provided in the contract specific prices of treatment rates of from \$7 to \$12 per ton, according to the grades of the ore, the agreement providing that if the Eagle Ore Sampling Co. shipped 1000 tons more or less of low value ore, the mill could demand and collect its minimum rate of \$7 per ton. Judge Riner decided that the ore still belonged to the sampling company, taking the position that a delivery for the purpose of treatment was not a delivery of sale, and hence this ore could not be included in the assets of the General Metals Co., nor could the moneys received for the same be diverted to the creditors in common to pay their debts.

#### Chaffee County.

At the Black Hawk mine, adjoining the Mary Murphy, at St. Elmo, work is to be continued by the Mary

H. M. Co., of which T. B. Crawford is president. The ore carries good values in zinc.

At Turret men are working on the Copper King in the south drift.

A copper discovery has been made near Mears, 9 miles southeast of Salda. The Evening Star group, located two years ago by F. H. Colvin of Salda, contains an 80-foot ledge of copper ore and has been opened up by four tunnels, making in all 1500 feet of underground workings. Negotiations are being made to build a mill on Poncha creek, 800 feet from the mouth of the main tunnel.

#### Clear Creek County

A strike has been made in the Seven-Thirty workings, near Georgetown, by O. Johnson & Co., operating under lease. J. Franchini & Co., who are also leasing in the Seven-Thirty, have found the same ore body 80 feet under where Johnson & Co. are at work.—Freisel & Co. are working a lease in the Seven-Thirty, east of the old workings and west of Johnson & Co.—F. G. Watrous and W. L. Herring of Boston have purchased the Big Clave claims and a tunnel site 2 miles from Idaho Springs, up Fall river.

#### Custer County

The Invincible shaft at Rosita is being unwatered preparatory to resuming work. The shaft is down 300 feet.—It is reported that C. W. Haskell, manager of the Molrose G. M. Co. of Silver Cliff, will put in a cyanide plant to work the ore from the Hector mine.

The California claim, on the north slope of Game ridge, near Custer, is to be worked. The shaft is 200 feet deep.

#### Dolores County

The Rico-Creede M. Co. has control of the Pro Patria mines and mills at Rico and is reopening the mine. The mill will be overhauled and remodeled. C. W. Rowe is manager.—D. Swickhimer writes from Rico that he has just made an important strike in the Logan mine on C. C. hill.

#### Fremont County

The Florence oil field is south of Florence in a structural basin, covering an area of 10 to 20 square miles. Oil has been found at almost all depths from 1300 to 3100 feet. The deepest well is 3650 feet, but no oil is known to have been found below 3090 feet. The oil is found in Cretaceous beds 4450 feet thick. Gas has been found at irregular depths in beds similar to those containing oil. Gushing is unknown in this field, but when oil is struck it usually rises several hundred feet in the hole and may approach the mouth of the well. Little water is found below the level of surface water. About 500 wells have been drilled, of which 175 have been producers and sixty at present pumping. It has proved unprofitable to pump where the wells yield less than seven barrels per day. The oil is high grade, being usually refined at Florence, and the wells have long life—five years or more.

The Fountain Park M. & M. Co. has started men at work in Junkins Park, near Florence.

The Empire Oil Co. at Florence has struck oil in its third well at a depth of 2095 feet. The oil appears to be of an excellent quality, and rose to a height of 50 feet. At a depth of 1500 feet the company opened a flow of gas, which is used for drilling purposes, thereby eliminating the expense of oil.

#### Gilpin County

E. W. Williams, E. A. Whitmore, the H. Paul estate, E. W. Rogers, J. Leidinger, H. Oranhood of Denver, C. L. Harker and J. H. Kent have sold the Addude, Good Luck, Poor Luck, Bushwhacker, Formosa, Fontaine and Teegeeatch claims, all in Russell mining district, to an Eastern company, who will develop the properties.

Leahy, Barnes & Co., leasing the U. P. R. lode at Mountain City, near Central City, will put in a hoist and clean out and retimer the shaft to a depth of 200 feet. The property is owned by the Gregory Buell Co., of which R. L. Martin is manager.—It is reported that the Hubert mine, in Nevada, is to resume operations.—During an electrical storm, the shaft building of the East Notaway mine, in Lake district, near Central City, was struck by lightning, setting fire to the structure and completely destroying it. Four hundred and fifty pounds of dynamite were stored in a magazine in one end of the shaft house when the lightning struck the building. When the fire reached the powder an explosion occurred, which tore the top, building to pieces and shattered the windows in the Gulch and Pittsburg properties nearby. So strong was the explosion, drills and other miners' tools were thrown 500 feet. The detonation of the dynamite was doubtless all that saved the machinery from complete ruin. When this exploded the building was torn down, and the flames were thus prevented from reaching the engine and boiler. The East Notaway is owned by the Town Topics G. M. Co. S. A. Joseph of Denver is manager. The shaft house will be rebuilt. Hoisting will commence before the shaft house is finished.—Peters, McCoy & Co. have taken a lease and bond on a property at the head of Gambell gulch, near Perigo, owned by Cochran, Hughes & Co., and have begun operations.—The Gold Dirt mill, near Perigo, is nearly completed. Work is going on steadily in the mine, and when mill and mine are working together a large force will be employed.—The Colorado tunnel, operated by Augustus & Co., is in over 500 feet and the ore body and the value of the ore is increasing as the tunnel is extended. They are moving their mill from Lump to Gambell gulch.

On account of the heavy rainy season, the Pewabic mine at Russell Gulch has had to contend with a considerable flow of water in the 400-foot works, so that development had to be stopped. Above the 400 the output averages 400 tons daily. The company has a lease and option on the New York mill, in which it intends to treat the entire product of the mine. The iron shaft on one of the Pewabic properties is to be equipped with a shaft house and machinery.—A straight shaft is being sunk on the Happy Hollow group near Gambell gulch, being operated by the Interstate Con. M. Co.—A contract has been let for another 100 feet in the Golden Sun M. & M. company's tunnel up South Boulder creek from Central City.—It is reported that the Copper Six M. Co. will resume operations on the Sampson claims in

Leslie gulch, which are owned by Messiter, Converse & Co. of Central City and Apex.

Regarding the 10-stamp mill being put up at the Gold Dirt mine, General Hall says each stamp weighs 1300 pounds and will be rapid-drop—96 to the minute. These stamps are expected to crush fifty tons per day. The first amalgamation on plates will be followed by regrinding to 100 mesh in Huntington mills, the pulp being elevated by sand pumps to four settling cones. The sands from the bottom of the cones can be drawn off at will and spouted to either of the four revolving agitating barrels, which are 8 feet in diameter by 12 feet long, placed underneath. Cyanide solution will be pumped into the settling cones. The agitating barrels revolve in cyanide solution and the extraction is finished in six hours. These results are all based on a series of experiments conducted in a 10-ton plant last summer, the extraction being 55%. After the extraction is completed, the solution is drawn off and the pulp washed to recover what remains. The tailings are dumped into receiving bins, elevated and distributed onto dumping tables, where it is concentrated. The overflow from the settling cones is leached by percolation and compressed air agitation. This plant will be completed during June.

#### Gunnison County

The Gold Cup mine, near Tin Cup, is being operated by the East Gold Hill M. & M. Co., of which I. L. Johnson of Denver is president and general manager. The main incline is down 900 feet with a drift 300 feet north, where it cuts the vein. The company has started a 3000-foot tunnel on the opposite side of Gold hill and has it in 200 feet. This work will cut the veins 200 feet deeper than the bottom of the main incline. The incline will connect with the tunnel.

An air compressor, hoiler and electric light plant are being placed at the mouth of the Carter tunnel, on Ohio creek, near Ohio City. The tunnel is in 1400 feet, and will be driven 3000 feet to the Volunteer ground. C. Carter has charge.—The Gold Links tunnel, near Ohio City, is in 1600 feet, and has cut two good veins.—W. Scott is making preparations to develop the Williams, near Ohio City, and put in a steam hoist and other machinery.

#### Lake County

The affairs of the Sedalia mine in Evans gulch, near Leadville, have been settled and a contract has been let to sink the shaft another 100 feet, giving a depth of 1000 feet. M. McHale has the contract.

#### La Plata County

A rich strike has been made in the Bullion Mountain M. Co.'s mine in the Needle mountains, near Durango. The ore is high grade and assays run high in silver, gold and copper. The strike was made in a tunnel 800 feet from the portal, and the vein was followed 125 feet, when it widened to 30 inches. J. Bloom is superintendent and E. M. Whiton general manager.

#### Pueblo County

It is reported that molybdenum has been discovered 3 miles east of Pueblo by H. H. Bourne.

#### Saguache County

P. R. Harpel, president and manager of the Steel Canyon M. & M. Co., in which every man employed is a stockholder, has ordered a concentrating mill of 100 tons capacity. The Steel Canyon mines are in the mountains bordering the San Luis valley, near Villa Grove.

#### San Juan County

At the Waldron property, in the Mineral Point district, near the headwaters of the Animas river, above Silverton, owned by the Adelia M. Co., the shaft is down 250 feet. Manager Lowe states that they will spend \$25,000 on the property, which, it is thought, will carry the shaft to a depth of 400 feet and a drift of 500 feet. Ore is awaiting shipment to the Durango smelter.—The Old Hundred mine, northeast of Silverton, is to have a new 40-stamp mill.

It is reported that the Bullion Mountain M. & T. Co. have struck high-grade ore on Needle mountain in their 1400-foot tunnel.

The Joe Gibbons M. & M. Co., working claims above Silverton, is building a new power house, 30x35 feet, and when completed a water power plant is to be put in to operate the mine machinery. A new mill may be put in this season.

#### San Miguel County

The San Miguel Examiner reports that the Black Bear property, in Ingram basin, near Telluride, is capable of producing a steady output sufficiently large to supply a mill and that L. Kaanta, president and general manager of the Black Bear M. Co., has been securing mill sites and has an option on the Fraction placer at Pandora, where the Smuggler-Union mills are located and where the Japan-Flora M. Co. expects to construct its plant. Manager Kaanta has also an option on five acres of land at the Silverton railroad, on the Red mountain side of the range, from the Smuggler-Union M. Co. On one of these sites a mill with a capacity of 200 tons daily will be built this summer. An aerial tramway is to be built to connect the mines and mill. A new air compressor is to be put in. It is also proposed to extend the crosscut tunnel, which now stops at the vein, through the mountain to the Red mountain side of the range, a distance of 3000 feet.

It is reported that the stockholders of the Smuggler-Union M. Co. are realizing larger dividends from the operation of the Smuggler-Union mines under the leasing system than at any time since they were purchased five years ago. From 1900 until June 1, 1904, when the mines were let out in blocks to leasers, they were worked and managed by the company. In this period only one dividend of \$60,000 was paid. The big leasers, who commenced operating in the summer of last year, are paying good royalties and making money. King & Lindsey are employing 100 men and keeping 50 stamps in the Smuggler-Union mills at Pandora, 2 miles above Telluride, supplied with ore. The Telluride Leasing Co., composed of I. R. Bancroft, A. R. Townsend and A. Brodine, employs seventy-five men, and their output keeps thirty stamps in one of the mills pounding. Wagner Bros. have a long-time lease on the 76 claim, on the Smuggler-Union vein, also a lease on the old dumps of the Smuggler, Union and Sheridan mines.

#### Summit County

At the King Solomon M. & T. Co.'s mine near Frisco, Engineer Montgomery is putting in an air compressor and drills.—At Frisco, the Mary Verna Co., J. E. Parker, manager, expects to order a compressor and air drills.—The Breckenridge Bulletin reports that the Old Union M. & M. Co.'s mill is being put in shape for running under the direction of C. J. Gilbert. The jigs, tables and screens have received the necessary readjustment to suit the ore as shown by the test runs and rearrangement in the classifiers and conduits has been made. A new ore feeder is being put in to feed the ore to the rolls. The main tunnel breast is in the ledge and the tunnel is in 730 feet.

In the Upper Blue river section, at Hoosier pass, between Summit and Park counties, the Hoosier Gulch M. & M. Co. is sending in machinery for its lode works. The placers are still blocked with snow.—M. Hoskins of Leadville and D. M. Gray of Canon City are buying machinery to start work on the Sallie Barber lode, on Nigger hill, near Breckenridge.

#### Teller County

The Granite mine on Battle mountain, Cripple Creek, is producing 1000 tons a month, the values running \$40 to the ton. The company is working eighty men. Most of the ore is coming from between the 800 and 1000-foot points.—The Home Leasing & M. Co. has been incorporated by A. Jones, D. J. McNeill, M. Gardner, T. A. Tallen and J. J. Sullivan. The new company will operate ground under lease, at present working on the Home claim.—On Rosebud hill and in the draw between it and Beacon hill, Cripple Creek, sinking is in progress on the Mary Nevin, Black Jack, Grace Arthur, Texas Girl and Rocky Mountain.—The ore shoot in the Russell shaft of the Independence Con. Co. on Bull hill at a depth of 210 feet measures from 12 to 20 inches in width and through the vein runs a streak of talc in which the high-grade values are found.—On the Clara D. property, Cripple Creek, Lessee McDonald has opened up a new ore shoot. They are taking out seven to eight carloads of ore per month.—Gardner and associates, operating through the main Clara D. workings, are working on their new find, breaking a body that runs from 2 to 3 feet in width, the ore averaging \$30 a ton. Operations are confined to the surface in the East Nellie V. claim.—Lessee Ford and associates, operating a block of the Jeff Davis claim of the same company, are sending out regular shipments.—Lessee Bradner and associates, operating on the Ocean Wave, Cripple Creek, have opened up 4 feet of ore at a depth of 100 feet. A carload of screenings taken from the ore shoot gave returns of \$49.60 to the ton.—Lessees operating the Gould property, Cripple Creek, who are confiding their development work to the Ophelia tunnel, are drifting in a low-grade ore.—Lessees operating on the John A. Logan mine, owned by the Stratton Cripple Creek M. & D. Co., are taking out ore on the extension of the Gold Sovereign dyke, which was opened in the Logan territory at the 500-foot level. The Gold Sovereign dyke is expected to dip out of the Logan territory, but the operators estimate that they will get from 50 to 70 feet of the ore shoot before it leaves them.—Sinking has been resumed at the Nugget shaft of the Legal M. Co. at Cripple Creek. It is proposed to sink from the 300 to the 400-foot level and start drifts in search of a flat vein believed to cross into Nugget ground from the El Paso and the C. K. & N.—Superintendent E. Taylor expects to resume sinking in the Raaler shaft of the C. K. & N. as soon as it can be unwatered.

The production of Cripple Creek district for May was as follows:

	Tons.	Average Value.	Total Value.
Smelters.....	8,000	\$75 00	\$600,000 00
Portland.....	7,500	28 00	210,000 00
Economic.....	5,500	35 00	192,500 00
Wild Horse.....	2,000	6 00	12,000 00
Anaconda.....	2,000	5 00	10,000 00
Homestake.....	6,000	2 50	15,000 00
Santa Rita.....	465	6 00	2,790 00
Micherardo.....	450	3 50	1,575 00
U. S. R. & R.....	25,000	30 00	750,000 00
Dorcas.....	2,200	32 00	70,400 00
Totals.....	59,115		\$1,864,215 00

The Byerly cyanide mill of Gillett has added a roaster.—Selbach & Johnson, leasing on the Pride of Cripple Creek, have let a contract to sink the shaft an additional 150 feet. The shaft is down 150 feet. The Fenway M. & M. Co. has started a tunnel through this property on Straub mountain near Cripple Creek. The bore has already been driven 170 feet.

The Merger G. M. Co. is sinking the Bonnie Nell shaft on Raven Hill, Cripple Creek, to the 1000-foot level.—The Gold Nugget Leasing Co., operating the Nugget claim on Beacon hill, Cripple Creek, have let a contract for sinking a shaft to a depth of 400 feet, which, when completed, will give it a total depth of 600 feet.—A larger crusher has been put in at the King & Craig mill, on the south slope of Gold hill, near Cripple Creek.—A lease on the Louisiana lode of the Ore-Or-No-Go Co., on the southeast slope of Raven hill, Cripple Creek, has been secured by C. F. Springer of Colorado Springs.

#### IDAHO.

##### Custer County.

J. A. Czizek of Loon Creek, west of Custer, reports good progress in the construction of the new smelter, although much material on the way is delayed by the bad roads. The smelter will have a capacity of 100 tons daily. He is driving a tunnel to the Montana vein. The mine is connected by a wagon road with Custer.

##### Idaho County.

L. Phelan has discovered a rich lead on the South Fork, near the Smith ranch, near Warren.—The Monongahela Co., operating in the Thunder Mountain district, has been reorganized, being succeeded by the Braddock G. M. & M. Co., organized at Braddock, Pa., the stockholders being the same as were owners in the old corporation. W. Forsythe is president and W. A. Gardner secretary.

##### Lemhi County.

A cyanide plant is to be added to the mill of the Gold Dust mines near Leesburg.

## Nez Perces County.

W. A. Nehrhood, manager of the Hy-Bar M. Co., working a cyanide plant to extract the values from the black sands of the Snake river bars, is putting in an experimental plant 3 miles above Lewiston.

## Owyhee County.

A 350-foot raise is being made from the Addie tunnel, near Silver City, to connect with a shaft on the Calaveras claim; it is up 150 feet. A drift south from the 100-foot point of the upraise has struck good ore. Work is being pushed on the upraise so as to improve the ventilation. A. J. Orem is superintendent. He is also said to have charge of work which has been started on the Trade Dollar Extension.—R. L. Hopkins, in charge of the California mine on War Eagle mountain, near Silver City, has men running a drift north from the shaft, on the 100 level, and is in now 80 feet. The vein has widened to 14 inches.

## Shoshone County.

Injunction proceedings have been commenced at Wallace by H. S. Jones, who is seeking to restrain W. R. Swicegood from working on the Mammoth tramway and extracting or removing ore therefrom. Jones alleges that he had a lease from the Federal M. & S. Co. which entitles him to the possession of the Mammoth tramway and ore bins. The complaint recites that while Jones was in the possession of the property, May 22, Swicegood, without any right, ejected him, and has since excluded him from the ground. It is alleged that since that date Swicegood has extracted from the tramway ore valued at \$600, which he threatens to remove. The court is asked to restore the property to the plaintiff and eject the defendant.

T. Anderson of Wallace, one of the stockholders of the Rex M. Co., has a year's lease upon the property. The lease covers the Sixteen to One, the Bimetallic Fraction and Ambitious claims, and the mill, tramway, water rights and machinery. It is stipulated that the lessee work steadily and continuously with a reasonable force employed underground, and to treat the ore in the mill as it is extracted. The company will receive a royalty of 25% of the net smelter returns. Anderson agrees to sink a winze at least 100 feet lower than the present lowest tunnel level.

The Cornucopia G. M. Co. has been formed at Wallace by F. Frohling, Murray, C. W. Betts, Murray, J. P. Sheehy, Wallace, G. Steward, Wallace, and W. W. Woods, Wallace, to work the Golden Gate Fraction, Spokane, Golden Slipper and Cornucopia lodes, in Summit mining district, east of Murray.—The electric power line of the Oom Paul mine is completed, the hoist is in position and ready to begin sinking. The electric line is strung on the Federal poles from Butte to the power house, thence across the mountain to the mine. The hoisting plant is underground.—M. H. Hare represents an Eastern company proposing to dredge placer ground on Oro Fino creek, near Pierce.

## Washington County.

The Weyant M. Co. has an option on the Rock Flat M. Co.'s properties, near Meadows, and has C. H. Nazro examining them.

## KANSAS.

During May in the Kansas, Indian Territory and Oklahoma oil fields 375 wells were completed, of which 257 found oil, 50 were gasers and 68 failures. On May 31 there were 42 rigs and 235 drilling wells in the field. This field has an area of nearly 11,000 square miles and extends from Paola, in eastern Kansas, southwestward 200 miles to Muskogee, I. T., and Cleveland, Okla. Most of the wells are operated by companies which lease the land on royalty. A number of independent refineries are being built in Kansas. Since 1896 operations in the Kansas field have been largely in the hands of the Prairie Oil & Gas Co., the Kansas branch of the Standard Oil Co. The oil has an asphaltum base and is dark brown or black in color, and varies greatly in specific gravity in different localities.

## MONTANA.

## Jefferson County.

The Basin Reduction Co., operating the concentrator in Basin, intend enlarging the mill this summer. The series of Callow settling tanks put in last year have proven a success, and the company has purchased thirty more, which will be put in together with fifteen tables to take care of the product from the extra tanks. The tail race has been extended and the water is run into cars, allowing the tailings to settle in the cars, the Great Northern railway using the tailings to fill in the bridges and trestles along their line. This system is temporary, and as it has not proved a success they plan to build a tail race to run over a series of settling tanks, and when these are filled the contents can be dumped directly into cars, the whole to be enclosed in a building that will be so arranged that it can be heated by steam during cold weather, allowing the work to go on at all times.—The Morning Star mine,  $\frac{3}{4}$  mile from Amazon station, near Boulder, owned by S. Myhre, has been leased and bonded by the Amazon-Butte M. Co. A 35 H. P. boiler has been put in and a hoist capable of sinking 300 feet. The shaft is being cleaned out to the 125-foot level when they will crosscut to get the lead. W. R. Evans of Butte is president.—Hart & Stephens of Butte have taken a lease and bond on the Dewey, 1 mile from the Morning Star, and are crosscutting the tunnel for the lead.

## Missoula County.

J. A. Scott, president of the Kennedy Creek G. M. Co., reports that his company is building a ditch from Butler creek to carry more water to their place, 32 miles from Missoula.—A. L. Thurston has bonded the interest of his partner, G. Cox, in the Rough Rider claims, 6 miles from De Borgia.

## Silver Bow County.

(Special Correspondence).—The copper production of the Butte district for May was 23,220,000 pounds, the various companies contributing as follows: Boston & Montana (Amalgamated), 6,076,000 pounds; Anaconda, Washoe, Parrot, Trenton and Butte & Boston (Amalgamated), 13,702,000 pounds; United Copper, 3,730,000

pounds; Clark mines, 3,627,000 pounds; North Butte (Speculator), 1,085,000 pounds. The Parrot, one of the Amalgamated mines, was closed by injunction during nearly all of May and its production of about 35,000 pounds a day cut off, but the shortage was made up from other Amalgamated mines, the output from which was temporarily increased. The average value of the ore shipped from some of the Amalgamated mines was also higher than April. The Rarus mine of the United Copper was also shut down for a while.

The daily yield of ore and pounds of copper for May was:

	Tons of Ore.	Pounds of Copper.
Boston & Montana.....	2,800	196,000
Anaconda, etc.....	6,800	422,000
United Copper.....	2,000	130,000
Clark Mines.....	1,800	117,000
North Butte.....	500	35,000

Butte, June 5.

## NEVADA.

## Lincoln County.

G. Freeborn is working properties on Pinto mountain, 3 miles north of Searchlight.—The shaft of the Searchlight M. & M. Co. at Searchlight has been straightened under the direction of Superintendent H. E. Carter and the hoist is being placed. A 30-ton roller mill is to be put in.—The Bamherger-De Lamar mine at De Lamar is opened by levels to a depth of 1000 feet. The main working tunnel is in 3700 feet. Water is pumped 14 miles from Meadow Valley where the electric power plant is also located. According to the Searchlight, the mill treats 11,500 tons monthly, being hauled from the mine by an electric locomotive. After preliminary crushing the ore is crushed in Chilean mills in cyanide solution and then conveyed to settling tanks, separating sands and slimes which are subsequently treated separately. The sands remain in the tanks for treatment by .3% cyanide solution and the overflowing slimes are treated by decantation and agitation. The water consumption is 118 gallons per ton of ore crushed. A new 600-ton mill is being built to treat the old tailings dump.

The California-Utah G. M. & M. Co. is working the Amethyst-Wild Irish mine, at Pikes Diggings, near Fay. The Amethyst shaft is to be sunk from the 130 to the 200-foot level and a double-compartment shaft will be sunk on the Wild Irish and connection made with the Amethyst shaft. D. K. Kilbourne of Los Angeles is interested in the company.

E. H. Hackett, superintendent of the Newport & Nevada at Deer Lodge, 24 miles from Uvada, Utah, is adding cyanide vats to the company's mills to treat the tailings. As soon as this is done the mill will start up.

## Lyon County.

The Goldfield Exploration Co., of Salt Lake, through O. A. Tibbetts and F. A. Flindt, have taken a bond on the Dyer copper claims, south of Yerington, and will develop them.

## NEW MEXICO.

## Grant County.

The Detroit-New Mexico M. & D. Co. is working placer ground on Whitewater creek, 3 miles from Central, using hydraulic giants and centrifugal pump.

## Luna County.

The smelter at Deming is to be blown in this month.

## Rio Arriba County.

M. J. P. Gill has resumed operations on placers at Hopewell after fighting water.—Superintendent Robinson has commenced unwatering the shaft of the Red Jacket, in Bromide district, preparatory to resuming work. The machinery for the mill is being hauled from Tres Piedras and is apt to be at work some time this month.

## Santa Fe County.

A pneumatic concentrator has been constructed in Tuerto canyon, near Golden, by the Pneumatic Concentrator Co., in which P. Kleck of New York is interested. Operations in the mill are to begin on June 15. The mill has 200 tons capacity and the cement tested carried from \$3.50 to \$5 free-milling gold per cubic yard. Previous attempts to extract these values have been unsuccessful.

## Socorro County.

E. Craig, manager of the Ernestine M. Co., says that the 500-ton concentrator and cyanide mill at Cooney is shipping \$30,000 worth of concentrates to the El Paso smelter every month. Three air drills have been operated in the main shaft, which is down 1100 feet.

## OREGON.

## Baker County.

A. Geiser, who is operating the Bonanza mine near Sumpter under lease, says that work is progressing on the 200-foot level and that the ore body recently exposed is proving rich. The mill has been started.—More men have been put to work at the Standard mine in the Quartzburg district. A sawmill is to be built and many other improvements made.—The E. & E. mine at Bourne is cutting a station below the 200-foot level to establish pumps and other equipments preparatory to sinking the main shaft.—The Connor Creek mine, bonded by P. Basche of Baker City, is to have a new 10-stamp mill.

J. A. Wilson, superintendent of the Mayflower mine, in Cornucopia district, states that work in the long crosscut to tap the main Mayflower and four other parallel veins is in progress and work is also being done in level 2 blocking out ore for the mill soon to be put in.—Work has been resumed at the Golden Chariot mine, near Sumpter. As soon as the hoist is ready, it is the intention to unwater the shaft and finish crosscutting to the vein on the 100 level, after which it will be extended an additional 200 feet.

The Indiana mine, 23 miles east of Baker City, is being developed under the management of J. W. Messner.—T. H. White, T. W. Ayers and H. J. Stillman of Pendleton have formed the Gold Coin M. Co. to work claims near Durkee.—The Queen of the West Mines Co., whose property adjoins the Cornucopia mine, has purchased a 10-stamp mill to be put up this summer. C. F. Soderling, president and manager of the company,

states that they are building an aerial tramway 3100 feet in length from the tunnel to the prospective millsite, and are also building 2 miles of roadway from Cornucopia to the mine.

## Jackson County.

The Lucky Bart mill, on Sardine creek, started its stamps on ore taken from the Corporal G mine. This property is owned and being developed by J. R. McKay of Gold Hill.

L. B. Chase and S. M. Rhodes of Ashland, developing a vein on Cantrall gulch, 2 miles west of Jacksonville, have made a shipment of smelting ore.

## Josephine County.

The Rogue River M., S. & P. Co. has been formed with D. C. Westlake of Grants Pass as president and W. E. Williams of Wilmington, Ohio, as secretary. C. N. Jones of Portland will have charge of the building of the proposed smelter near Grants Pass, and W. I. Fleck of Grants Pass will be consulting engineer. A Corliss will be superintendent and will have charge of the work on the smelter building and the dam. C. L. Proehstel will be assayer and chemist for the smelter. The site for the smelter has been selected at Savage Rapids, on Rogue river, 5 miles east of Grants Pass. The company proposes to put in a dam in Rogue river and supply water and power for irrigation purposes. The dam is being built with the slag from the smelter.—The Rogue River M. & L. Co., under the management of L. W. Smith, are prospecting their gravel deposits on the left fork of Fooths creek, near Grants Pass, by drifts being driven through the channel showing a deposit to have a depth of not less than 30 feet.—While waiting for their electric machinery the Champlin Dredging Co. on Fooths creek are prospecting their ground on the right fork of the stream and halting the ground ahead of where work is to be resumed. Holes are drilled to the bedrock at 50 feet apart and charged with 100 pounds of dynamite. It is estimated that each shot will loosen 3000 yards of gravel at the cost of 1½ cent per yard, and will facilitate digging when work is resumed.

## SOUTH DAKOTA.

## Lawrence County.

(Special Correspondence).—The Tinton Co. has engaged F. R. Carpenter as general manager of its gold and tin mines in the Bear Gulch and Nigger Hill region. Dr. Carpenter was the first engineer to make a careful examination into the character of the tin-bearing deposits of the Black Hills, while dean of the School of Mines at Rapid City. Later he built and operated the Deadwood & Delaware pyritic smelter at Deadwood. The tin veins of western Lawrence county are dikes of pegmatite granite. These dikes are of very coarse crystallization, containing white and rose-colored quartz, mica, and various feldspars, abundant tourmaline, apatite, and the more rare iron ores, such as wolframite and columbite, with cassiterite. In many respects the tin ores of the district resemble those of the Harney Peak region in the southern Black Hills. A testing mill has been built at the mines at Tinton and a large tonnage of ore treated by concentration.

Spearfish, June 3.

(Special Correspondence).—At the Wasp No. 2 on Yellow creek, 2 miles from Lead, another of the great blasts for which this mine has become famous is in preparation. The ore lies in a nearly horizontal bed. A series of deep holes is drilled and these are sprung repeatedly with nitro powder, and the final blast is prepared by mixing black and nitro powder. A few months ago a blast of this kind was reported to have dislodged 6000 tons of ore, mention of which was made in these columns at the time. The ore is low grade—\$5 per ton—but it is successfully treated by the cyanide process at a profit. Wolframite has been profitably mined at this mine. This ore also contains gold.

Lead, June 2.

The Horseshoe mill is to be rebuilt either at the old millsite at Terry or at Pluma. The company is working the Ben Hur and McDonnell regularly, and is shipping ore to the smelters. R. N. Ogden of Deadwood has been appointed receiver of the affairs of the Horseshoe M. Co. upon application by the Hearst Mercantile Co. The appointment was asked for merely as a measure of safety and to save cost to the company. There are a number of liens, amounting to \$30,000 and over, unpaid, and other claims against the company that may become liens. These would result in numerous lawsuits unless some proceeding like the present was taken. Production from the mines will continue, ore shipments going to Omaha smelters, the Lundberg, Dorr & Wilson cyanide and a small amount to the Imperial mill.—F. E. Little of Minneapolis, president of the Minnesota M. Co., working near Maitland, intends to put in a 200-ton mill.—The Gladiator Co. has men drifting on the Red Cloud group, near upper Deadwood gulch.—The Deer Lick Co., operating on Deer creek, west of Spearfish, has placed orders for a hoist, boilers, air compressor, drills, pumps, etc., and expects to put them in and begin active development. Figures on a 100 ton cyanide plant are being secured.

## Pennington County.

The Canton Co., of Hill City, is preparing to put in a mill.—Manager E. J. Kennedy of the Golden West Co. reports a successful run at the company's new mill on Castle Creek near Rochford. The mill operates by water power; a bucket tram transports ore from the mine bins to the mill; in the big quarry or open cut a belt conveyor is used to transfer ore to the bins. It is possible that a cyanide annex may be added to the present amalgamation mill.—Hydraulic mining at Placer-ville, on Rapid creek near Pactola, is being carried on with four nozzles at work on the bar, handling 2600 yards of gravel daily. This ditch is 4 miles in length, 8 feet wide and over 4 feet deep, and runs from Pactola to Placer-ville. At present the operations consume 2760 miner's inches of water, but with the addition of more nozzles all the water in Rapid creek will be used, over 4000 miner's inches. L. A. Richards is manager.—E. C. Johnson is unwatering the Gertie mine,  $\frac{1}{2}$  mile south of Hill City. A mill is being put up to treat the ore, which carries values in tin and gold.

## UTAH.

## Salt Lake County.

The Boston Con. Company at Bingham will drain the Copper Central tunnel and crosscut from it to open up the new strike being developed from the Peabody tunnel. The Copper Central tunnel is in 3500 feet on the south side of the property. The Highland Boy storehouse at Bingham has been doubled in size. The Red Wing air compressor and drills in Bingham canyon have been started up.

It is reported that a shaft is to be sunk upon the Maxwell group, at Bingham. New machine drills are to be put in at the Fortuna mine at Bingham, the air to be secured from the Dalton and Lark.

## Summit County.

At the Comstock mine at Park City two pumps are handling the water. Superintendent Jas. Hickey expects to strike the ore body soon. Work has been commenced at the Columbus mine, near Park City, under the direction of F. A. Bird.

## Utah County.

The Buckley mine in Rock canyon, east of Provo, is under the management of the Woodward Bros., who are working two shifts to finish the shaft, which will connect the upper workings with the lower tunnel, from which they are now taking ore.

## WASHINGTON.

## Ferry County.

Work has been started by the Keller & Indiana Consolidated Smelting Co. on a 150-ton smelter at Keller. A 50-ton sampling plant is to be put in. Electricity generated by water power on the San Poil river is to be used as power.

## WYOMING.

## Carbon County.

The alterations to the concentrator of the Penn-Wyoming Co., at Encampment, have been completed and the mill started. The tramway is bringing down ore from the mine and the smelter should soon be in operation. It is stated that work is to be resumed on the Continental C. M. Co.'s property in the Cow Creek district, near Battle. The Gertrude Co., at Battle, will commence sinking as soon as heavier machinery can be put in.

## Fremont County.

The South Pass gold mining district, 40 miles south of Lander, consists of a belt of metamorphic schist 20 miles long and 15 miles wide, cut by dikes of diorite, and auriferous quartz veins. It lies at the foot of the Wind River mountains, and is drained by the Sweetwater river and its tributaries, Gold, Pine, Willow, Rock and Strawberry creeks, all of which have produced placer gold.

## FOREIGN.

## AFRICA.

Barretts-Berlyn is said to be one of the cheapest-worked gold mines in the world. At the Pilgrim's Rest venture during the year ending February, 1905, 9s. 1d. per ton covered all expenses. The ore treated is a brown tuffaceous earth averaging in value about 4 dwt. per ton. During the year the deposits worked yielded good supplies of low-grade ore, the following tonnages being dealt with, namely: Ore mined and sent from Bannister's Reef, 9490 tons; slimes from reserve, 2145 tons; total, 30,374 tons, the whole of which was treated by direct cyanidation and produced 5718 ounces of gold, realizing £18,977, and gave an average extraction of 3 dwt. 18 gr. per ton. The cost of production was further reduced during the past year to 9s. 1d. per ton, the lowest figure ever reached by this company. After charging all items of expenditure, both in London and South Africa, writing off large amounts of repairs, loss of livestock, depreciation in the market value of investments, prospecting work, etc., the financial position has improved to an extent of £5403, which amount has been applied to the reduction of last year's deficit of £15,560, bringing the debit balance down to £10,157.

## AUSTRALIA.

## New South Wales.

The total value of the mineral output of New South Wales in 1904 was \$32,012,790, an increase of \$1,431,520 on that of 1903. The total number of persons employed is estimated at 37,837. The value of the plants in operation in metalliferous mines, including the dredging plants, is \$10,157,180. The gold yield for 1904 was 269,778 ounces fine, valued at \$5,730,545, showing an increase of 15,557 ounces and \$330,400 in value, as compared with 1903. Cobar is the principal gold field of the State, with an output of 61,734 ounces fine, valued at \$1,311,065. The Mount Boppy gold mine is the largest of the State. The value of the yield obtained by the dredgers was \$1,249,180. The Araluen division is the principal center of gold dredging operations, with fourteen plants at work during 1904. The dredging for tin is now a firmly established industry, and the quantity of tin ore saved by these plants during the year amounted to 319 tons, valued at \$130,900. The number of dredging plants in commission at the end of 1904 was forty-two, valued at \$1,177,880.

## CANADA.

## BRITISH COLUMBIA.

## Boundary District.

Work has been resumed on the Don Pedro in the Lake group in Skylark camp, owned by the Chicago-B. C. M. Co. It is expected that the long tunnel on the Betts and Hesperus group, Hardy mountain, 4 miles from Grand Forks, will soon tap the main ore body at a depth of 225 feet. A. D. McPhee, superintendent of the McKinley mine, north Fork of Kettle river, near Franklin, reports that the tunnel has tapped the ore vein after driving 94 feet.

The Great Northern has had a number of ore cars built that will hold 50 tons each of Boundary ore. They

were constructed specially for use on the run between the Granby mines and smelter. They will arrive in time to be used when the daily tonnage is increased by 700 or 800 tons, which will be when the new furnaces, now being installed at the smelter, are in operation—some time in July. Three groups of mines in the Boundary are now being exploited with the diamond drill. For eight or ten months the Granby Co. has had Boyles Bros. of Spokane, Wash., doing this work on the Monarch and adjoining claims, and it still continues. The British Columbia Copper Co. is operating its own diamond drill at its Mother Lode mine in Doodwood camp, and L. D. Wolfard, president of the Wellington Co., has Knight & Stone of Spokane at work on the Wolfard group, where a contract has been made for a starter of a thousand feet of holes. F. M. Elkins of Greenwood and W. E. Hodges of Vancouver have given a bond of \$125,000 on the Fairy Queen claims, near the Kingston group in Hedley camp. W. E. Collis and associates of Victoria have taken the bond and are expected to start development work shortly.

## East Kootenay District.

The two additions to the St. Eugene boiler and compressor building at Moyie are finished and ready for the new 20-drill compressors and boilers. The St. Eugene mines are owned by the St. Eugene Con. M. Co., James Cronin, manager, at Moyie. The workings extend along the St. Eugene outcrop for 4300 feet, the upper workings being 1800 feet higher than the lower ones on the shore of Moyie lake. Until recently mining has been entirely by adit tunnels on the vein, with stopes therefrom. On the highest workings of the St. Eugene there are five tunnels about 100 feet apart vertically; the intermediate workings have four tunnels and the lake shore four tunnels, No. 1, 100 feet above the lake, being in 1700 feet. Near the mouth of this tunnel a shaft has been sunk 125 feet and levels run in both directions. The ore from the upper workings is carried to the mill by an aerial tramway, that from the lower workings and shaft 1/4 mile on a surface tramway. The ore is galena in a quartz matrix, and as mined, carries from six to eight ounces silver and 13% to 14% lead, which is concentrated in the mill to thirty-three ounces silver and 66% lead. The daily output is 400 to 500 tons. The work of putting in the foundation piers for the steel tippie at Coal creek, 5 miles from Fernie, is proceeding rapidly; twenty-five are completed and twenty-five more are under way. There are 135 piers altogether. Speaking of the contract between the C. N. P. Coal Co. and the miners, President Sherman of the union stated that the wage schedule for the past two years had been improved in some cases. Fire bosses received a raise of 35 cents per shift and blacksmiths got a slight increase. The equal distribution of cars was one of the several working conditions which were improved.

## West Kootenay District.

The 10-drill compressor for the Silver Dollar mine, on Mohawk creek, in the Lardeau, is being packed in over the trail in small sections. The Silver Cup mine, near Five Mile, in the Trout Lake division, is working a full crew under the direction of T. Baribeau. The ore is treated in the combination concentrating, chloridizing and amalgamating plant operated by Ferguson Mines, Ltd. Acting Manager E. G. Hadrow describes the process as follows: The fine ore passes through grizzlies and the coarse through two Blake crushers into storage bins below. The twenty 1000-pound stamps each crush four tons per day through a 16-mesh screen. The pulp is classified into coarse and slimes. The coarse is passed into biddles, where most of the barren sand is removed and the galena separated from the remaining sulphurets, this product from the biddles being shipped as concentrates to the Trail smelter. The remainder, consisting mostly of zinc blende, tetrahedrite, iron pyrites and some sand, is thrown on to a storage floor and left to drain. The slimes are passed into spitzkasten and the surplus water removed. From there they are passed on to two Frue vanners, the headings from which pass to the storage floor below and are mixed with the tailings from the biddles. After draining, the product is dried in a revolving drier and heated with the waste gas from the roasters. There are two White-Howell roasters, into which the ore is charged with the requisite amount of salt and chloridized. It is then charged into amalgamating pans and the gold and silver amalgamated. The mill is operated by water power.

## Nelson District.

The Board of Trade of Nelson has passed a resolution that it is their wish that the payment on the bounty of lead ore be not extended after June 30. The opinion is that the bounty law is not a success.

## JAPAN.

The new mining law of Japan is now in effect. Its principal provision from the foreigner's view is that it debars any foreigner from owning or working mines in Japan.

## MEXICO.

## Chihuahua.

G. G. Gillette of Parral sold the Quebradillas mine of the Quebradillas M. Co. to M. J. Condon, J. W. Connor and C. F. Hunt of New York. J. W. Connor will be manager of the new company to be called the Veta Colorado M. & S. Co.—G. G. Gillette and associates have bought the Iguala mine near Parral and will put in a hoisting and pumping plant.

D. M. Evans of Parral has a concession to build a smelter of 250 tons capacity, combined copper and lead, says the Chihuahua Enterprise. The concession was granted to D. M. Evans, S. Garrison, W. J. McMarlin and S. F. Lathrop, the last four being of Pittsburg, Pa. The location is 4 miles below Parral on the Mexican Central Railroad, convenient to the copper and lead mines owned by companies of which Mr. Evans is general manager. The Guadalupe mine is copper and the Providencia and Big Four group are lead. It is proposed to build a wire tramway from the Guadalupe mine to the smelter, which will be 1 1/2 mile long. The concession is for fifteen years, with the usual exemptions from State and municipal taxes. The minimum capacity to be allowed is 80 tons daily, but the plan is to build at once

a 250-ton plant. This corporation will be controlled by the Guadalupe M. Co., the Big Four M. Co. and the Providencia M. Co.

The American S. & R. Co. has commenced a three-compartment shaft on the Velardena mine at Santa Eulalia. On the Nueva Chihuahua at Santa Eulalia J. Mitchell will sink a shaft. Escobar & Ross are drilling a well near the Dolores mine. If water is struck they propose pumping the water to their jig concentrating plant, which is said to have treated the Dolores ore very successfully. It is reported that L. Ruth and C. Smythe are preparing to put in a smelter near Arechuyvo. Ruth & Smythe represent J. E. Carnahan, a steel manufacturer of Canton, Ohio. They have copper properties in that district which they have been working for two years.

## Oaxaca.

The Mexico Gold & Silver M. Co. will build a 10-stamp mill at Santiago Minas, Oaxaca, where it is operating four properties—the Noche Buena, Providencia, Santa Rosa and El Sol. Ore running over 400 ounces silver per ton is reported in the Noche Buena. The general offices of the company are in St. Louis. E. C. Rendell is president, E. J. Krauss, vice-president, and C. F. Hoanel, secretary.

## Commercial Paragraphs.

E. M. HERR has been elected first vice-president Westinghouse Electric & Manufacturing Co., Pittsburg, Pa.

J. K. FIRTH, JR., is assistant district manager Wagner Electric Manufacturing Co., 417 Rialto Building, San Francisco, Cal.

THE Jeanesville Iron Works, Hazleton, Pa., has established a New York City office at 1 Broadway, with H. W. Weyhenmeyer in charge.

"ADVERTISING FOR PROFIT," 5th edition, from the Manufacturers' Advertising Bureau, 126 Liberty St., New York City, gives several capital pointers to the modern trade journal advertiser.

KNUT POSSE, M. E., for the past twelve years with Fraser & Chalmers, and their successors, Allis-Chalmers Co. of Chicago, has resigned his position to assume charge of the mining department of Chalmers & Williams, who have established their works at Chicago Heights, a suburb of Chicago, with main sales office at room 1553, Railway Exchange, Chicago.

THE Utah Mining Machinery and Supply Co., Salt Lake City, Utah, are installing twenty more Callow tanks in the Callow slime plant at the Heinz concentrator, Basin, Mont. They also have orders from the Boston & Montana Co., Great Falls, Mont., for the first unit of Callow tanks in the 3000-ton concentrator of the B. & M. They are making shipments of these tanks into Arizona, Mexico and Canada.

THE Homestake M. Co. has adopted pneumatic haulage for its gold mines at Lead, S. D., and has placed an order with the Ingersoll-Sergeant Drill Co. for a duplex four-stage Corliss air compressor to supply the power. Fourteen pneumatic locomotives will supersede the present mule service. The compressor to supply air at 1000 pounds pressure for this service is stated to be the largest high pressure compressor in the world.

THE Compressed Air Machinery Co., 24-26 First street, San Francisco, Cal., have leased the spacious premises 25, 27 and 29 Stevenson street, giving them an additional 76x100 feet which they will use as a machine shop on the ground floor for the manufacture of their air compressors, drills, drill making and sharpening machines and mine hoists. This adjacent property will afford room for needed enlargement. The office and salesroom will be retained, corner First and Stevenson streets.

THE Prinz & Rau Mfg. Co., Milwaukee, Wis., have just received through their representative, J. P. Sterling, Kansas City, Mo., an order for two large Perfection dust collectors, with steel drums, from the Dorcas Mill, Mining & Development Co. of Florence, Colo. This order is in addition to a number of machines they are now using. The Prinz & Rau Mfg. Co. are receiving quite a number of inquiries for their machines from all over the mining districts. These machines have been proven a success in saving dust and fumes which contain large values.

A. P. HEAD, London representative Wellman-Seaver-Morgan Co., Cleveland, Ohio, has completed a tour around the world, during which he established the following sub-agencies for the company: Melbourne—Australian Metal Co. as Australasian agents. The branches of this concern are as follows: New Zealand—The Gilbert Machinery Co., Wellington; Queensland—J. Stothert, Brisbane; N. Queensland—J. Croker, Mackay; New South Wales—W. R. Laidley, Sydney; South Australia—J. C. Fraser, Adelaide; West Australia—A. E. Thomas, Coolgardie; Tasmania—L. Tullock, Launceston. In India the following agencies, representing the presidencies of Bombay, Bengal and Madras, were appointed: J. Harper, Calcutta; F. Harrison, Bombay; W. H. Oakes, Madras.

CARY & FIELDING, 1711 Tremont St., Denver, Colo., have an order from the Old Hundred mine, near Silverton, Colo., for a complete concentrating mill. The mill, when completed, will have a capacity of 400 tons per day and consists of twenty-eight Card tables, forty 1300-pound Boss stamps; crushers, boilers, Cameron pumps; seven alternating current generators; shafting, pulleys and belting. The building is to be of steel and a portion of the walls to be of cement and floors of cement. The mill will cost approximately \$150,000. They also report the sale of Rand compressors as follows: One to Pride of West mine, Silverton, Colo., one large Imperial type to the Vidler tunnel, Georgetown, Colo.; one to Delta, Colo.; one to Colorado Springs, Colo.; two to South Dakota; one to Central America; one to Wallace, Idaho; one to Georgetown, Colo.; also, seven Cameron pumps for different sections.

## Books Received.

"Contributions to Economic Geology, 1904," S. F. Emmons and C. H. Hayes, geologists in charge, Bulletin 260 of the United States Geological Survey. This is the third bulletin of a series prepared to give prompt publication of the results of economic geological investigations. They are condensed to meet the wants of the busy man, much of the material to appear later in more elaborate form. The papers are grouped according to the subjects treated and at the end of each section is given a list of previous Survey publications on that subject. The volume is a valuable one and should be in the library of every mining man. It is sent free upon application to the Director of the United States Geological Survey at Washington, D. C. Under the head of gold and silver, W. Lindgren writes on the production in the United States in 1904, and other writers describe special districts in California, Colorado, Maryland, Nevada, Utah and Washington. Tin, molybdenum, uranium, vanadium, copper, lead and zinc, iron and manganese, coal, petroleum, natural gas and asphalt, building stone, cements, clays, salt, gypsum, sulphur, phosphate, mica, graphite, abrasive materials and hot springs are each discussed from an economic standpoint.

"Terminal Harbors of the Panama Canal," by L. W. Bates, is a monograph stating conditions at the Panama and Atlantic termini of the Panama canal and suggesting the formation of artificial lakes and locks as an aid to the project. It is an elaboration of parts of the author's previous monograph on "A Project for the Panama Canal." It includes maps of Panama and Limon bays and relief views of the isthmus.

## Trade Treatises.

The Replodge Governor Works, Akron, O., send a standard catalogue descriptive of their new mechanical relay governors.

Catalogue "A" from the Denver Balance Co., 3000-3006 Larimer street, Denver, Colo., illustrates and describes their pulp, assay, and analytical balances.

## Obituary.

E. J. PITHEY, cashier of the Utah Con. mine, died at Salt Lake, Utah, June 3, aged thirty-five years.

A. J. C. FAYE, New York manager Joseph Dixon Crucible Co., died in New York, May 26, aged 72.

W. S. DYER, a pioneer miner of Siskiyou county, Cal., was found dead in the tunnel of his mine, near Gazelle, Cal., June 1.

J. S. HAMMOND, superintendent Rawhide mine in Tuolumne county, Cal., died in San Francisco recently after having been crushed by a cave in the mine.

P. L. KIMBERLEY, president Balaklala Con. Co., died in Chicago, June 4, of apoplexy, aged fifty-nine years. He had been in many mining enterprises throughout the West and was a pioneer in copper mining in the Lake Superior regions.

W. C. JUTTE of Pittsburg, Pa., died May 24 at Atlantic City, N. J., aged 44 years. He was interested in the Monongahela & Western Dredging Co., the Jutte & Foley Contracting Co. and the Pittsburg Gravel & Dredging Co.

E. J. BONSTELL died of yellow fever at Panama on May 22, being on his way to take a position with the Darien G. M. Co. Mr. Bonstell had made his home in California for several years past at Sutter Creek, coming from the Tintic district of Utah. He was an expert miner, an assayer and a successful cyanide and chlorination man.

## Dividends.

Bunker Hill & Sullivan M. & C. Co., dividend No. 93 of \$1,500,000, June 5th; total paid since January 1st, 1905, \$2,175,000; total to date \$4,446,000.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MAY 30 1905.

791,327.—PIPE ELBOWS.—D. F. Asbury, Seattle, Wash.  
791,000.—CHEESE SCREEN.—W. H. Bartels, Fruitvale, Cal.  
791,244.—SHAFT BEARING.—Carpenter & Baker, Los Angeles, Cal.  
791,411.—FIREARM.—C. Freeman, San Diego, Cal.  
791,024.—PAPER FILE.—T. P. Gower, S. F.  
791,190.—GATE.—L. Hanson, Cottonwood, Idaho.  
791,419.—BRAKE SHOE.—F. A. Hawk, Central Point, Or.  
791,150.—RAIL CLEANER.—G. Huff, Tropic, Cal.  
791,207.—BRISTLE DEVICE.—P. H. Rogers, San Bernardino, Cal.  
791,037.—LUBRICATOR.—P. Le Sueur, Calabasas, Cal.  
791,187.—STONE SAW.—A. H. MacNutt, S. F.  
790,909.—FRUIT WASHER.—L. McCann, Ontario, Cal.  
791,044.—METER DIALS.—J. M. McPheters, Everett, Wash.  
791,158.—UMBRELLA RACK.—A. Mikulich, Sacramento, Cal.  
791,302.—THE PLATE.—A. A. Mott, Summit, Cal.  
791,300.—OILING DEVICE.—R. Nelson, Los Angeles, Cal.  
790,974.—CAR BRAKE.—J. C. O'Neill, S. F.  
791,106.—RAILWAY TIE.—J. E. Owens, Porter, Wash.  
791,305.—OIL BURNER.—P. J. Owens, S. F.  
791,309.—INDEX.—E. Peycke, Los Angeles, Cal.  
791,210.—MOTOR VEHICLE.—R. M. G. Phillips, Los Angeles, Cal.  
791,356.—WAVE MOTOR.—T. Rapp, Los Angeles, Cal.  
791,292.—VEHICLE WHEEL.—J. C. Rencherford, Paradise, Ariz.  
791,318.—SAWHORSE.—W. S. Schuyler, Oceanside, Cal.  
791,219.—HOG TRAP.—W. S. Schwartz, Perrydale, Or.  
791,372.—HORSE BLANKET.—R. A. Seaders, S. F.  
791,290.—JOINTS.—H. E. Smith, Roslyn, Wash.  
791,051.—NUT LOCK.—A. P. Steel, Stockton, Cal.  
791,060.—PICTURE HANGER.—B. G. Wallace, Portland, Or.

## Latest Market Reports.

SAN FRANCISCO, June 9, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.50@15.50; Electrolytic, 1 to 3 casks, \$15.50; Casting, 1 to 3 casks, \$14.75@14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £65 11s 3d spot per ton.

Within the week copper had shown an advance of ½ cent per pound, to 15.5c. There is no indication of further immediate advance, but there is no evidence nor any apparent reason for a lower price than that to-day quoted.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 18s 8d long ton.

SPELTER.—New York, \$5.30; St. Louis, \$5.70; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.87½; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 35@37½c. London, £136 7s 6d.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, 3½c; dust, 3½c, 10c; sulphate, 3½c, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c. ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.35; gray forge, \$16.00; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@23.00; open hearth billets, \$23.00@23.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 3c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 3c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl. CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail.) Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00@shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb., 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2\*, 35%, carload lots, 9½c; less than one ton, 11c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 11½c@7c; caustic potash, 10c in 40-lb. tins; rolf sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, boiled, bbl., 62c; cs., 67c; raw, bbl., 60c; cs., 65c; Lucol oil, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 18c; As; tral, 18c; Star, 18c; Extra Star, 21c; Eocene, 20c, Elaine, 26c; Water White, in bulk, 11½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera;

Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naptha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 53@68c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, per lb., 80c.

URANIUM.—Oxide, per lb., \$3.50.

MERCURY.—Bichloride, per lb., 77c.

TUNGSTEN.—Best, per lb., \$1.25.

PHOSPHORUS.—American, per lb., 70c.

SODIUM.—Metal, per lb., 50c.

BISMUTH.—Subnitrate, per lb., \$2.10.

SILVER.—Chloride, per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, per lb., 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

PROCESS OF REFINING SUGAR.—No. 790,036. May 16, 1905. Felix Deusy, San Francisco, Cal. This invention relates to improvements in treating sugar molasses, and pertains especially to the refining of the sugar and the recovery of the salts of potassium in the molasses as nitrate of potash. The object of the invention is to provide a method of treating the molasses and the exosmose water so that not only a very much larger percentage of sugar may be recovered than by ordinary methods, but there shall be saved all the values in the form of salts of potash. It consists in the process of treating molasses and as a part thereof, the osmose of the initial molasses, the mixing of the osmose molasses with a sugar-syrup solution, boiling this mixture in grain, centrifuging the boiled mixture, dissolving the sugar so separated and refining this solution.

SUBMARINE CAISSON AND TUNNEL CONSTRUCTION.—No. 790,046. May 16, 1905. Peter J. Gildea, San Francisco, Cal. The object of this invention is to provide a means by which large spaces of ground covered with water may be laid bare, so that men and machinery may be safely employed at all such works as mining, excavation, building, recovering lost valuables, etc., and the structure may be of sufficient size to incase the hull of a vessel or other sunken structure. Means are provided for connecting the working interior portion directly with store-rooms and an ingress chamber with interposed air-locks, and the whole is surmounted with a platform, with means for communicating directly between said platform and the interior of the caisson. The apparatus is provided with ballast-chambers having longitudinal partitions to prevent the ballast from shifting and independent air-chambers, with means for filling or emptying them. It consists of an inverted double-walled shell with intermediate truss-frames, a superstructure fixed upon the top of the caisson having chambers at opposite ends and having interposed air-locks, means connecting one of said chambers with the interior of the caisson, means connecting the other chamber with a platform above the surface of the water, a platform and framework whereby said platform is supported from the caisson above the surface of the water.

HALF-TONE SCREEN HOLDERS FOR PHOTOGRAPHIC CAMERA.—No. 790,290. May 23, 1905. James S. Ditty, San Francisco, Cal. This invention relates to an attachment for cameras and is especially designed for cameras which are employed for the production of half-tones and the like in photo-engraving. It consists of an independently adjustable hinged frame carried upon the camera and movable to vary the space between the screen and the photographic plate. The invention is designed, first, to permit the operator to vary the distance between the screen and the sensitized plate at will, to remove the screen frame and its parts from the plate holder, and the danger of destroying these parts by coming in contact with the solution which will drip from the wet plates which are used. It also makes it practical to photograph both line work and half-tone on the plate, thus giving a uniform stipple over the entire plate or picture photographed.

TELEPHONE CALL ATTACHMENT.—No. 790,684. May 23, 1905. Joseph Harverson and John Mudgett, Santa Cruz, Cal. This invention relates to a telephone call attachment especially adapted for use in central offices to make connection on party lines. It consists of a revolvable mounted toothed disk, connections by which an electrical circuit is intermittently completed by the contact of the teeth of the disk with the contacts of the screen and the contact disk having depression in its periphery, a revolvable shaft, with which the depression is normally coincident, and means including a push member, a bell crank lever actuated thereby, and a pin on the second disk engaged by said lever, for turning the second disk so that its periphery will contact with the revolvable shaft and complete a revolution of itself in the toothed disk.

WINDOW-SHADE ADJUSTER.—No. 790,703. May 23, 1905. William C. Organ, Oakland, Cal. This invention relates to means for adjusting window-shades with relation to the windows to which they are attached, so that such shades may be bodily raised or lowered with relation to the window opening, and by such means the shade may be placed at the top of the window or at such intermediate position of its height and independent of the rolling and unrolling of the shade. It consists of vertical tubular guides fixed upon each side of the lower part of the window frame, rods slidable in said guides having heads at the upper end, a connecting bar by which said heads are united, a cord having one end centrally attached to said bar, a locking pulley in the top of the window frame over which said cord passes whereby the slidable frame may be raised, lowered and fixed at any point, and a shade roller having hearings in the heads of the sliding bars below the transverse connecting bar.

GATE.—No. 791,190. May 30, 1905. Louis Hanson, Cottonwood, Idaho. The object of this invention is to provide certain improvements in hinged swinging gates, by which improvement the gate may be raised or lowered and means provided to adjust it to swing free of snow or other impediment. A suitable latch is provided and means for operating said latch from either side, so that the driver may open and close the gate without leaving the vehicle. It consists in a gate having the hinges, and the posts upon which they are turned, in combination with a catch having a counterbalance plate to the outer gate post, a spring-pressed latch pivoted to the gate, bell-crank levers having their angles pivoted to the gate, a flexible connection from one arm of each lever to the latch and a flexible connection extending from the opposite arm of each lever whereby the latch may be lifted.

UMBRELLA RACK.—No. 791,158. May 30, 1905. Andrew Mikulich, Sacramento, Cal. The object of this invention is to provide a simple, neat appearing, compact, and practical rack of this character which can be manufactured and sold cheaply, which is adapted particularly for use in restaurants, hotels, stores, and generally in places, which can be attached to a wall, post, counter, or other suitable support, and which will occupy very little space. The device comprises a casing provided with a drip-chamber, a coiled spring just above said drip-chamber, said casing having its front extended above the chamber and conforming substantially to the outline of the spring, said casing open at the top and said front provided with a projecting portion adapted to direct the drip from the umbrella into the chamber.

## Summer Time in Alaska.

Recently there has appeared in these pages a number of interesting illustrations of winter scenes on the Yukon and in Alaska. During the long winters the miners and others make lengthy pilgrimages from place to place by means of sleds drawn by horses or dogs, and transportation by this means is convenient and comparatively inexpensive. As a matter of course the routes chosen for travel by sleds lie along the water courses and lakes, for the mountains are usually so abrupt as to make them impassible barriers to the traveler. With the coming of spring the ice in the rivers breaks up and later the streams are free from ice, and navigation is open for a few months. One of the accompanying engravings shows the appearance of the river during the period of breaking up of the ice. At this time it is not safe to venture to make an extended journey for fear of blockades and ice jams. Another illustration is that of Eagle City, as seen from the bluffs above town. Eagle City is near the international boundary and on the American side. A third engraving gives a good idea of a Yukon river steamer, and the character of the landings at some of the points along the river. These vessels are all flat bottomed and have stern wheels. Many of them have paid for their construction many times over. A glance along the bank

A View on the Yukon Near Eagle City. The Photograph Was Taken at Midnight June 30, 1904.

Steamboat Landing at Eagle City, Alaska.

of the river shows the rather frail character of the buildings, but what is more surprising, several cattle as well as horses are seen. At present the most

important gold mining region near Eagle City is on American creek, and its tributary, Discovery Fork. In 1903 a flume was built on American creek having

a capacity to carry 1200 inches of water. The flume was nearly  $1\frac{1}{2}$  mile in length and 150 feet head was available, it being the intention to employ hydraulic elevators, but with the coming of summer it was found that the available water supply was insufficient for the purposes, and during 1904 the plant was remodeled and further experiments tried, to make as effective use of the outfit as possible. Several creeks below Eagle City which are tributary to the Yukon from the west have been worked for several years past with good results. One of the most recent discoveries in this region was the upper basin of Washington creek late in the summer of 1904. One nugget weighed \$168, and there was much coarse gold found. What this new district will develop the present year remains to be seen. There are good prospects opposite Eagle City on the Yukon, but water was found below the level of the frozen ground which rendered efforts to work it abortive, for the time being at any rate. The fourth engraving of this group is most interesting. The photograph from which this engraving was made was taken at midnight on June 30, 1904. At this season of the year at the latitude of Eagle City—about  $65^{\circ}$  N.—it is daylight, and objects can be seen for miles on all sides. A few degrees farther north the sun is in sight at the midnight hour, which has given to this north country the name of "the land of the midnight sun," but the midwinter days are of only a few hours duration.

THE recent decision of Judge Beatty of the United States Circuit Court, denying the injunction against the several mining companies, asked for by farmers in the Coeur d'Alene district of Idaho, has taken a proper and common-sense view of the situation. He correctly concluded his decision by remarking that the granting of such an injunction would result in closing down the mines and the depopulation of the district.

THERE appears to still be, in certain localities, some misunderstanding concerning the effect of forest reserves upon the mining industry. It is not the purpose of the reserve to oust the claim owner, nor to prohibit the prospector from entering the tract set aside as a reserve to carry on his search for minerals. The purpose of creating forest reservations is "to improve and protect the forests within the reservations, or for the purpose of securing favorable conditions for water flows, and to furnish a continuous supply of timbers for the use and necessities of the citizens of the United States." The proclamations setting aside certain tracts as forest reserves provide for preserving the status of mining claims valid and subsisting at the date of the withdrawal of the land from the public domain. The object of the reserve is not, as some think, to antagonize the mining industry, but to protect the timber from destructive fires and wanton waste, in order that it may be used in the industry of mining and otherwise, and also to protect the watershed as far as possible and to secure by this means a permanent rainfall, for it is a well established fact that where the timber has been burned or cut off from large areas the water supply in the lands below, to which such area is tributary, soon fails, and the summer supply is inadequate or disappears altogether. Un-

der such conditions the soil is swept away and the run-off becomes very rapid and the springs soon disappear.

## Value of a Mine Cost Sheet.

A great deal has been done in the past few years to reduce mine account keeping and the preparation of cost sheets to a science, and much that is commendable and useful has been evolved; but, without doubt, the "system" can be carried to a point beyond which it ceases to have practical value. What the mine superintendent wants is a system of cost sheets made up from the office books which will enable him at any time in a very few minutes to arrive at the cost of any particular piece of work which has been accomplished under his direction. It may become necessary to cut out a station and ore pocket at the commencement of operations in opening a new level in the mine. The question arises: "What will be the cost?" He turns to the cost sheet which gives this information for similar work at some higher level. Here he finds the dimensions of the cutting. The amount of materials and their cost is stated—timber, chute doors, track, lights, installation of the bell signal system, labor, drills, etc., explosives and every detail in connection with this work, both above and under ground. If any difference in conditions exist, he should be able to determine what they are and estimate accordingly. By a comparison of several such sheets, which represent the cost of two or more stations, the superintendent may see where the cost of doing the new work may be reduced. The idea applies not only to cutting and equipment of shaft stations, but to every department and class of work about the mine, whether under ground or on the surface. To make the scheme of the cost sheet available and as nearly accurate as possible, the warehouse account must be kept as carefully as that of a merchandising store. Not a rope, nor a valve, a can of oil or any of the many small items, which go to make up the whole, should be given out (much less taken without leave), until a requisition blank has been filled out and filed by the proper person, presumably the storekeeper, showing for what purpose the article indicated is to be used, and where. This is to be signed by the foreman, or stamped "O. K." by the storekeeper, who later submits it to the foreman for verification. These slips are collected from the various departments daily by the bookkeeper and entered in the books. Where some such system is not in use, the loss of fittings and supplies during the year about a large mine would pay several times over for a force of expert bookkeepers and store tenders to look after this branch of the business. There are many things essential to the success of operating a mine beside the foreman's time book, and even the time book should be kept in such a manner that it will show the number of hours of labor put in on any particular class of work. In the mine some of the men (laborers generally) are employed at half a dozen different tasks during a shift. A man may be assisting for an hour in track laying. Then for an hour or two he is required on the air-pipe line, or on the pump, or he may have to help in the mucking gang. Again, he is sent to the surface for some particular purpose, and is thus shifted about from place to place. It makes no material difference in his pay, but neglect to keep account of this division of the laborer's time will make a great difference in the cost, as shown on the books, of any particular operation. It is unsatisfactory to apportion labor costs in the office by guess, as is often attempted.

One of the most difficult matters to keep track of is the proper division of expense of power in operating air drills. The only proper method of arriving at this is to keep as accurately as possible the number of hours each machine is employed on every shift, and to divide the monthly cost for air compression by the number of drilling hours, when the drilling time of each machine may be ascertained by consulting the drill sheet and the proper charge made. By this means the cost of drilling operations may be very closely arrived at. In drilling cost must be included deterioration of machines, repairs, lubrication, and blacksmithing on drill bits, cost of steel, etc. These charges, together with labor, explosives, timber, tracks and ventilation, make up the main expense of the various mining operations. Superin-

tendence and general expenses must also be considered, but these are incidental and cannot be avoided. The more extensive the operations are the less the general expense charge should be against any particular work in the mine.

## Steel in Mill Construction.

The disadvantage in not employing steel and sheet metal in the construction of mills was again illustrated in the complete destruction of the large cyanide mill of the Horseshoe Mining Co. at Terry, S. D., a few days since. The building caught fire in the crusher department and spread so rapidly that it was impossible to save the structure or any part of it. The mill cost nearly \$500,000, and was insured for about one-half this sum. Undoubtedly the first cost of a steel structure would be much higher than one built of the native Black Hills lumber, but, had steel been employed, the building would have been still standing, and heavy insurance premiums, as well as the loss, would have been saved.

Several years ago the Deadwood & Delaware smelter burned, when the plant had been completed and was doing a satisfactory business—handling 400 tons of ore daily. The smelter was rebuilt of steel with double this capacity, but this did not save the loss of the cost of the plant destroyed. About a year ago the Val Verde smelter in Yavapai county, Arizona, was completely destroyed by fire, and, in addition to these, there have been numerous other serious fires of reduction works, all of which might have been prevented had the structures been of steel. Even more serious are the fires of shaft buildings, where the fire is likely to be communicated to the timbers in the shaft, as was the case when the hoist at the Union mine at Virginia City, Nev., burned last summer. Steel has been successfully used in the construction of head frames and also of mine buildings, and the sooner the practice becomes universal the better for the industry.

## Market Value of Mines.

An Eastern financial paper recently published a table giving the names of a number of important copper producers in the United States—their annual production in pounds, the present selling value of the stocks of these properties in the market, and the market capitalization per pound of copper produced. Of what value such a compilation can possibly be is not apparent, as there is actually nothing of value that may be derived from a careful study of such a table other than the incidental ratio shown by the figures. In the first place the amount of copper produced by any particular mine does not indicate that an arbitrary percentage of this value is disbursed in dividends, for it is not always the largest producer that makes the greatest percentage profit. Obviously a mine yielding 20% ore will be enabled to pay a larger proportion of its earnings in dividends than one which produces a 4% ore, even though the latter be one of the heaviest producers in the country. Another reason why such comparisons are of little value is, that the output of a mine for this year is not a safe index of its ability to produce next year. It may by increased development be enabled to greatly exceed the present output, or the ore bodies may become exhausted and the mine cease to produce altogether. The comparison of these several copper-producing properties above referred to is interesting, but of no real value in determining the present or the future value of these mines.

FROM almost every mining State and district comes the news of the reopening of old properties, or the development of new ones, while expansion in operations appears to be the rule with active, going concerns. Mining has come to be looked upon by conservative business men as a perfectly legitimate and safe business, when honestly conducted—a distinction which it did not enjoy a few years ago. The present attitude toward the mining industry on the part of conservative investors is largely due to the safeguards thrown around it by the responsible mining engineers. The experience of years has abundantly demonstrated that mining operations may be conducted with as much safety, viewed from a financial standpoint, as may be found in any other industrial pursuit.

## CONCENTRATES.

CONCRETE can often be used to good advantage at the collar of a mine shaft and sometimes underground.

IN laying mine tracks of T rails it is customary to place the joints of the rails between the sleepers, and not upon them. This usually gives better satisfaction.

WHERE a dump of mineral or waste, whether containing values or not, are left indefinitely on the land of another, it becomes the property of the owner of the land.

A LESSEE has the right to all minerals in the dump created by his labors during the term of his lease, but not afterward, unless specifically otherwise expressed in the lease.

THE pressure on the inner face of a dam is normal to that face, whatever the slope angle may be. On a face standing vertical the pressure is horizontally outward, on one sloping backward at 60°, the direction of pressure is downward at an angle of 30° from the horizon.

COPPER GLANCE is not readily soluble in dilute solutions of sulphuric acid, and any attempt to treat this class of ore by leaching would probably result in failure. The percentage strength of acid used in leaching oxidized copper ores depends upon the amount of copper present.

THERE are three types of flume construction, viz: the rectangular flume, the "V" flume and the V flume with flat bottom. To V flumes are sometimes added vertical sides to prevent the overflow of water from "jams" where the flume is used as conveyor of lumber, wood, or other material.

IT is not good practice to make a saw cut on mine timbers for the purpose of lining up, for in the event of this timber being subjected to pressure it is very likely to split at this cut, as it is weakened by it. It is not uncommon to see the under side of caps for drift sets and the wall plates of shafts scored in this manner.

SAWS used in marble and other stone cutting are not provided with teeth, but are simply bands of steel with unserrated edges, the cutting of the stone being accomplished by feeding sand and water under the saw. These saws are usually arranged in groups or gangs, so that several cuts may be made at one time, thus lessening the expense of cutting.

THERE is no reason why a brick or stone stamp mill may not be erected and run for years without excessive deterioration. Brick mills, built in 1877, were run for years without injury to the walls from the jar due to the falling stamps. It is necessary to have substantial foundations under such walls. A frame mill will not endure on insecure foundations.

EXCELLENT PERMANENT MARKS for the use of the mine surveyor are made by drilling a hole in the roof of the drift or other opening and driving into it a wooden plug. Into the plug at the precise spot should be driven a horse nail, through the flattened head of which has been bored a hole, into which a hook on the plumb-bob string or the string itself may be secured.

THE first patent issued by the United States Patent Office was on July 28, 1836. During that year a total of 109 patents were issued. During 1904, the number of patents issued was 30,267, a total to the first of January, 1905, of 748,567. This number has been since increased up to June 6, 1905, to a total of 791,992. At the present rate the number of patents issued during the calendar year, 1905, will exceed 80,000.

IT is not impossible for strata of limestone to lie between granite and greenstone. Such a condition is possible where the limestone has been intruded or uplifted by the granite with the subsequent intrusion of a greenstone dike which lies now on the hanging wall side of the limestone. Where intrusive rocks are forced into sedimentary strata, almost any kind of complication of geological structure may result.

IN working an ore body or vein up to a property line, the work of mining must be done in such manner as to prevent the caving of the adjacent ground of another proprietor into the mine workings thus made. The damage occurring from the undermining of the surface of another's property, where the surface has settled by reason of the removal of the ore or mineral, may be recovered by the injured party in a suit at law.

A ROCK DUMP 200 feet long, with a base of 130 feet and height of 30 feet, with a horizontal top cross section of 10 feet lying on a flat surface, will contain about 22,000 tons of material. It would cost to load this into cars by hand shoveling about \$3000, but various inexpensive devices can be arranged to load the greater part of the rock without shoveling, thereby reducing the expense from one-third to one-half. If a very large amount of

material of this kind is to be moved, it would be economy to put in a steam shovel.

THE vein of the Granite Mountain mine, near Philipsburg, Mont., occurred as a fissure at contact of granite and metamorphic sedimentary rocks, and the Drummond mine, near Marysville, at contact of schists and a mass of diorite. Some of the silver-bearing ores of the Butte district in Montana are wholly in granite. Many silver veins are in limestone, in andesite, rhyolite and a great variety of other rocks, both sedimentary and eruptive. Some of the sedimentary rocks are not even metamorphic, as at Silver Reef, Utah.

THE right of a mine owner to dump waste rock or ore on the lands of a lower proprietor has never been passed upon by the Supreme Court of the United States. It has been held, however, in one case (Equator Co. vs. Marshall, U. S. C. Court, Colorado), in an action brought to restrain defendant from dumping on lower ground of plaintiff, that as no actual damage was being done, no work retarded, shafts filled up, life endangered, or other gross or material injury inflicted, the remedy lay in a suit at law for damages if any damage were done.

ALTHOUGH multiple ropes are common on the elevators used in buildings, "Concentrates" knows of no instance where two or more ropes are used in mines for hoisting a single cage or skip. The system of winding in building elevators and in mines is entirely different. In the former the sheave is at the top of the shaft and the winding engine is at the bottom. In the latter the hoist is at the surface and the cage or skip is hoisted from below. The principle involved is similar in both, but it has not been considered advisable to employ multiple ropes in shaft winding, and in deep shafts it would be impracticable.

THE counter weight on the flywheel of a rock breaker, or on any other piece of machinery, is placed opposite the eccentric, or crank pin, as the case may be. The theory of the counter weight is to place a mass of metal equal in weight to the weight of the crankpin, cross-head and a portion of the connecting rod, at a point opposite this weight, or in the case of an eccentric opposite it. The instructions usually sent out by the manufacturers of rock breakers is to key the flywheel to the shaft according to marks made on the shaft. It is immaterial in which direction the flywheel revolves. The counter weight on either wheel should be opposite the eccentric.

THE small triangular projection seen at the apex of nearly every oil derrick is a device by means of which the drill hole is centered directly beneath the periphery of the crown wheel over which the cable supporting the tools passes. In the operations of drilling, drawing casing, and by other means, the derrick is often racked somewhat, which, owing to the height, carries the crown wheel out of direct alignment. This is detected by dropping a plumb line from the apex, when the derrick is "jacked" back into place, for if drilling be continued without taking this precaution the drills are likely to be deflected from a true vertical direction and the hole lost.

THE placer deposits found in some portions of California are very often not derived directly from the veins of the neighborhood, but may have been deposited and redeposited a number of times. There are instances where the gold in a placer mine is known to have been redeposited at least three times, and possibly in some instances a greater number. An instance may be mentioned occurring near Mokelumne Hill, in Calaveras county, where the gold originally derived from the auriferous veins was deposited in an ancient channel of the first period, which was subsequently cut by channels of the second and third periods, and the latter, exposed by recent erosion, formed a placer in a gulch, where it was mined in the early days. Here is an instance of gold having been deposited in a placer four successive times.

THE owner of a mining claim, patented or otherwise, upon discovering that the vein located passes out of the side line, may locate the extension of the vein on an adjoining claim, through the medium of a discovery made in driving a drift on the vein from the first claim into that located later, and if the original locator claims that assessment work for the second claim was performed in that first located, and can prove that such work was for the benefit of both, he may hold both claims by doing all the assessment work in the first claim. Sinking a shaft in this location might be claimed as development for the benefit of both. If B, thinking that A has abandoned the second claim, undertook to relocate it, he must make a discovery from the surface, in which A has the advantage of B, for the latter cannot claim A's discovery on the second claim, because he can only do so through becoming a trespasser on A's first claim. B must sink through the "wash" and make a bona fide discovery on the second claim, if he wishes to attempt to initiate title to A's second claim, and even then he runs the risk at first pointed out, that of having A say that he had no intention of abandoning this claim and did his assessment on the adjoining claim. Assessment work may be done on a patented claim for the benefit of an adjoining unpatented claim.

IT is not necessary to have double-tread rear wheels

on a skip to make it dump automatically if the skip is of proper construction. The side bars of the skip should extend well toward the bottom, or to the bottom, or lower end of the skip. All wheels may be of the same size and pattern (the ordinary flanged skip wheel). At the point of dumping the track turns from the incline of the shaft to a horizontal direction, and extends toward the rear from 4 to 8 feet or more, depending upon the length of the skip. When the forward wheels reach the horizontal section, which is approached by curving the rail from the incline, it runs forward on the horizontal section until it is stopped by a bumper. Meantime the rear wheels are lifted from the track by the continued pull of the rope, when, as the proper angle is attained, the contents of the skip are discharged into the bin beneath. The engineer releases the reel and the skip drops backward, the rear wheels striking the track and the vehicle descends into the mine. With a careful engineer there is neither danger nor difficulty. This device is in operation at scores of mines and has been for years. An elaborate device for dumping such as is often seen is not necessary. The above described scheme for automatically dumping skips has been also successfully applied to vertical shafts, but in such cases it is very important that the skip shall not be overwound or the skip will dump a portion of its load at least into the shaft.

THE rise in temperature in compressing air in the usual types of compressors found in the mining regions can be greatly reduced in most cases if the air be conducted to the compressing cylinders from the outside open air, instead of within the building, as is most commonly the case. The freezing up of an air pipe line during cold weather is due to the moisture in the air, which congeals, clogging the pipe. To obviate this difficulty a sort of condenser called an "aftercooler" is made through which the air passes, the moisture being condensed and settling to the bottom of the aftercooler from which it may be drawn off. If desired, the air, now comparatively free from moisture, may be reheated for use. A large-sized air receiver, situated 20 or 30 feet from the compressor, has a tendency to take a large percentage of moisture out of the atmosphere. Where the pipe line from the compressor to the point of use is long—over 1000 feet—it is good practice to put in a second receiver. It not only extracts more water from the compressed air, but gives a larger volume of air upon which to rely in case of a sudden unexpected stoppage of the compressor. At some mines having air-compressing plant, with water or electrical power, and steam (usually the original plant) as auxiliary, the air line is connected with the boilers when not otherwise in use to give greater capacity to the air plant.

FOLLOWING are tests for antimony (Sb.): Heated on charcoal before the blowpipe with sodium carbonate, antimony compounds are reduced to beads of gray, metallic, brittle metal, easily oxidized, and forming a white sublimate of antimony oxide on the coal, at some distance from the assay, coloring the flame greenish; the fused bead on removing the flame burns, forming crystals of oxide of antimony. The detection of the presence of antimony when in small quantities in an ore is a difficult and delicate operation, which requires considerable chemical knowledge and apparatus, and the same may be said of manganese when occurring in small quantities. If it occurs as black oxide it can usually be seen without difficulty. If as the carbonate or silicate, the mineral may also usually be seen. The oxides are black and often soft. The carbonate (rhodochrosite) is brittle, soft (3.5 to 4.5), luster vitreous, inclining to pearly, colors rose red, yellowish gray, dark red and brown, streak white, faces of crystals striated. The silicate of manganese (rhodonite) is often crystallized, with rounded edges, very common in tabular form, commonly massive. It often occurs as embedded grains; hardness 5.5 to 6.5; very tough when compact; luster vitreous, and on cleavage faces pearly; color light brownish red, flesh red, rose pink, sometimes greenish or yellowish; streak white.

QUARTZ CLAIMS may be located in the Dominion of Canada (which includes British Columbia) under the following laws and regulations: Persons of eighteen years and over and joint stock companies holding free miner's certificates may obtain entry for a mining location. A free miner's certificate is granted for one or more years, not exceeding five, upon payment in advance of \$7.50 per annum for an individual, and from \$50 to \$100 per annum for a company, according to capital. A free miner, having discovered mineral in place, may locate a claim 1500x1500 feet by marking out the same with two legal posts, bearing location notices, one at each end of the lode or vein. The claim shall be recorded within fifteen days if located within ten miles of a mining recorder's office, one additional day allowed for every additional ten miles or fraction. The fee for recording a claim is \$5. At least \$100 must be expended on the claim each year or paid to the mining recorder in lieu thereof. When \$500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at \$1 an acre. Permission may be granted by the Minister of the Interior to locate claims containing iron and mica, also copper, in the Yukon Territory of an area not exceeding 160 acres. The patent for a mining location shall provide for the payment of a royalty of 2% of the sales of the products of the location.

Chinese Methods of Mining Quicksilver.\*

Written by HENRY BRELICH.

The following notes refer to quicksilver mining in one of the remotest provinces of China, and, in addition to giving some insight into the habits and peculiarities of Chinese miners—points of vital importance to those who employ them, either in China or elsewhere—shows how their simple wants and cheap mode of existence enable them to make a living by mining low-grade ore in the most antiquated way, and smelting it with the most primitive appliances.

The Wan Shan Chang mines are the principal and most extensively worked deposits of quicksilver in Kweichow, and are representative of the conditions prevailing in other parts of the province—such as Pachai, Beh Mah Tung and Wuchuan. They are situated in the Prefecture of Toon-Yen in the province of Kweichow, about latitude 27° 30' and longitude 109° 0' E., at an altitude of 3000 feet above sea level.

The principal route to the mines is from Shanghai, along the Yang-tze-Kiang to Shasi, 903 miles, which is covered by river steamers, thence by junk along one of the numerous canals, and skirting the north-west corner of the Tung Ting lake, to the Yuen river, which is followed to SENCHI, 315 miles. From SENCHI the Mayang river, a tributary of the Yuen, is followed to Toon-Yen, 85 miles, thence overland to the mines, 21 miles. The journey may be accomplished under favorable conditions in twenty-five days.

The mines can also be reached by continuing the journey from SENCHI along the Yuen to Huang Chow, 195 miles, and then overland to the mines, 13 miles.

The distance of the mines from Shanghai is 1324 miles and 1426 miles, respectively, by these two routes.

The country in the immediate vicinity of the mines forms a nucleus whence several canyons radiate to the east, north and west. Southwards in the direction of the Yuen river, numerous conical hills with rounded tops and steeply inclined sides covered with shrub, and separated by narrow, tortuous, culti-

beds which have, in most cases, undergone considerable local disturbance.

There are two varieties of cinnabar which constitute the ore. One is a bright transparent red, the other a dark opaque red with which antimony is almost invariably associated in small quantities. The former is known as the "red," and the latter as "black" cinnabar. Pyrites is entirely absent. Native mercury is occasionally associated with antimonial ore.

**HISTORICAL.**—No authentic information can be gathered regarding the time when mining was first begun here. The landowners, who may be regarded as the descendants of the oldest families, claim that their ancestors carried on mining during the Ming dynasty (1368-1644 A. D.), but, beyond this rather vague statement, no data whatever can be obtained.

Previous to the introduction of gunpowder by Szechuanese miners some thirty years ago, mining was carried on with the hammer and gad, and in the larger workings by "fire setting." This mode of mining, as also the introduction of powder, is well remembered by the old inhabitants.

**POPULATION.**—The mountainous country surrounding the mines is sparsely populated when compared with the more fertile parts of the river valleys; and the number of inhabitants of Wan Shan Chang, within the area wherein the deposits of ore occur, which includes those in the mining villages and farmsteads, is estimated not to exceed 10,000.

The inhabitants may be divided into two distinct classes—mining and agricultural. The former are

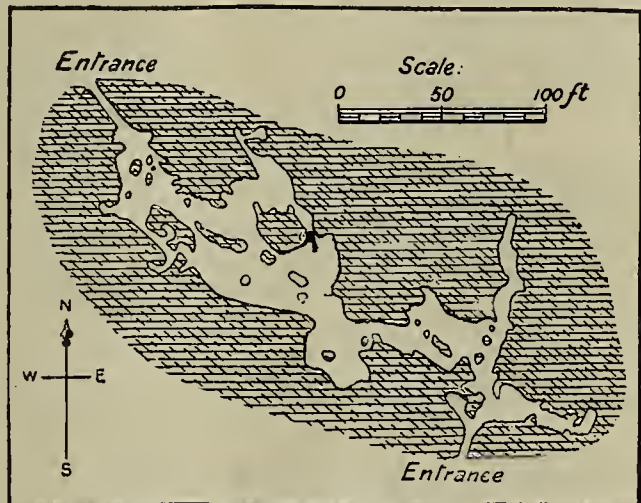

the huge mine dumps both inside and outside the mines.

The "ore pickers," as they are locally termed, are mostly lads, women and children, who may be seen wending their way in small gangs to the mines from a distance of 2 or 3 miles at all hours of the morning, armed with basket, hammer, rake and lamp, returning to their homes in the evening with ten to fifteen pounds of picked ore each, assaying 1% to 2% Hg, which is the usual amount gathered in a day's work.

**METHOD OF WORKING.**—The method adopted for winning the ore is to follow the mineral wherever it occurs, with an entire disregard for the most elementary rules of mining, which naturally results in a series of workings, intricate and tortuous beyond description.

The miner follows a stringer or leader on a mineralized band of ore, enlarging the working place to such an extent only as to enable him to work. In Fig. 1 is shown an old working said to have been abandoned some sixty years ago, where the ore from an irregularly mineralized bed of limestone 1 foot 6 inches thick has been completely removed by hammer and gad, the working averaging 3 feet 6 inches in height. The fact that the deposits are not deep-seated, and that the deeply carved and fissured country does not permit the accumulation of large quantities of water in the workings, has enabled the natives to carry on mining in their primitive ways without receiving the serious check which would have compelled the entire suspension of mining operations.

During the rainy season, the surface water which

Plan of a Chinese Quicksilver Mine.

Chinese Quicksilver Reduction Furnace.

vated valleys, form the principal features of the country.

The climate, though moist, is fairly healthy, and epidemics, which are so prevalent in many parts of China, have never been recorded here. The natives suffer mostly from fever, which, however, is frequently of a more severe type than ordinary malaria.

The rainfall and temperature is shown in the following table:

Date.	Average Max. F.	Average Min. F.	Rainfall. Inches.
1901.....	63.33	51.91	57.73
1902.....	66.51	54.84	48.39
1903.....	63.41	52.41	55.70

**ORE DEPOSITS.**—The predominating geological formation is magnesian limestone lying in almost horizontally stratified beds, which attain a thickness of several hundred feet, and extend over a considerable portion of this and the neighboring provinces.

The quicksilver deposits are scattered over an area of, roughly, 3 square miles, isolated and irregular in shape, and occupy a distinct zone in the limestone, those near the rim of the canyon being the most extensive and most productive, while the numerous smaller ore bodies, which occur some distance away from the canyon, are, with one or two exceptions, insignificant, and would probably have remained untouched in any other country as too poor for remunerative exploitation. The ore occurs:

1. Impregnating well defined beds of limestone.
2. Along the joints, cracks, and planes of stratification.
3. In isolated bunches, nests or pockets, and in vughs or cavities which contain crystalline aggregates or well developed crystals of cinnabar in the form of penetration twins of two rhombohedra associated with quartz and calcite.
4. Irregularly disseminated through a number of

constantly engaged in mining work, and depend for their living solely upon that source, although some at harvest time render assistance to the farmers. They work irregular hours of the day or night, according to their disposition, and are in no way bound to adhere to any methodical routine of work, which, by the way, is never practiced by the Chinese. Their meals, taken twice a day, consist principally of rice with vegetables, and more seldom pork, washed down by copious draughts of water, which is sometimes replaced by tea. Gambling and opium smoking form their only recreations, and there is but a very unimportant minority who do not indulge in both these, their favorite and ruinous pastimes.

The conditions underground are the worst possible; the workings are badly ventilated, and the air is made more foul by many of the men who live in the mine, fearing that their ore will be stolen if left without being watched. The oil used in the lamps burns with a lurid, smoky flame, the gases generated by the combustion of powder on firing remain in the workings and are inhaled by the miners, who, immediately the shot is fired, rush to the face to prevent others from stealing the ore.

Entirely ignorant of the simplest rules to be observed in regard to their bodily welfare, they are thus continually subject to the many injurious influences which surround them, resulting in this community being reduced to a most deplorable condition of health and suffering many ailments—the most prevalent being disease of the lungs. The stronger and healthier rural population of the surrounding country, whose constant work is in the fields in a comparatively healthy climate, contrast markedly with the mining class. They seldom seek employment in the mines, but during the winter months, when there is no demand for their labor in the fields, they devote a portion of their time to picking ore from

accumulates in the lower workings is forked by means of bamboo or wooden chain pumps, similar to those used for irrigation purposes. If the water cannot be coped with, the working is abandoned for the time being, and work resumed during the dry season. Timbering is unnecessary, the ground being compact and holding up well, even in the largest working.

Foul air due to the absence of ventilation is considered of no account, and men are often at work where, without approaching it closely, the smoky flame of the lamp can only be distinguished with difficulty.

The men will submit to constant discomfort in preference to executing any work which causes expenditure and is not directly remunerative. The ore is mined in the ordinary way by drilling holes, seldom beyond 15 inches deep, with  $\frac{3}{4}$ -inch iron drills pointed at both ends with steel. The holes are charged with two or three ounces of gunpowder by first inserting the pricker in the hole, then the powder, which is tamped with an iron rod, the tamping of clay or finely crushed rock, filling the hole almost to the rim. A pointed bar is inserted in the eye of the pricker, which is loosened by twisting and removed. The fuse is inserted in the space left by the pricker, and a conical shaped piece of paper is placed at the end of the fuse, which, after being lighted, smoulders, and acts as a time fuse until it reaches the powder.

The principal ingredients of the powder, niter and sulphur, are products of the province, and the explosive is made at the mine under circumstances which frequently lead to fatal injuries to those preparing it. Owing to the defective mixing of the three ingredients which constitute gunpowder, and to the inferior quality of the niter, the explosive force is not great, and an average shot breaks, roughly, 100 to 200 pounds of rock.

The mines may be classed as "private" mines,

\*Trans. Ins. Min. & Met.

acquired and worked by so-called companies, and "public" mines, worked by individual miners. In the private or company's mines the men are employed (a) on day's wages; and (b) on tribute.

In the first case the miners have to sharpen their own drills before going into the mine, and drill and fire two holes each about 15 inches deep, this being considered a day's work. They drill single-handed with hammers weighing six to seven pounds, one back hole counting as being equal to two down holes, while uppers they are unable to drill.

The men work on an average five to six hours per day, but no work is done on every fifth day, which is market day and also pay day, when they receive 400 cash (about 1s), in addition to the two meals, costing 50 cash (1.6d), with which they are supplied daily.

Overtime is paid for at the rate of 40 cash (1.2d) for each hole drilled in excess of two.

Thus, a miner working on day's pay earns, inclusive of his food, 130 cash (4.2d) per day, and makes at the most twenty-four hours in five days.

When working on tribute, the company assigns a portion of the mine to one or more men, who supply their own tools, explosives, etc., and are allowed to work without any restrictions, on the understanding, however, that the ore mined is to be retorted in the furnaces of the company, who retain a certain percentage of the quicksilver—i. e., the amount collected in the annular space of the furnace through the percentage holes, to be described later—and purchase the mercury produced at a stipulated figure lower than the market price.

The percentage holes are so arranged in the different furnaces that the amount of quicksilver varies from 20% in the case of poor ores to 40% in the case of rich ores.

The company pays all the taxes to the officials and landowners, howsoever the mine may be worked.

The public mines are mostly old workings which have been abandoned as too poor to be worked by a company, but still rich enough for individual miners, who, on payment of a "hammer" tax of 600 cash (1s 7d) per month to the local magistrate, are allowed to work in any unoccupied mines within a limit, vaguely defined, "of 10 feet." If the ore is won in sufficient quantities, the landowner establishes a furnace near the mine, and the miner is compelled to have his ore treated in it, the owner retaining the usual percentage collected through the percentage holes, which is seldom, if ever, below 20%.

**TREATMENT OF ORE.**—The ore is sorted in the mine, and brought to the surface in bamboo baskets of a capacity of thirty to forty pounds, fastened on the back of the carrier by ropes, which pass under the armpits. It is then cobbled and picked, and as much as possible of the barren rock removed, and after detaching any large crystals of cinnabar with a pointed piece of stout wire, it is crushed to pass a  $\frac{1}{2}$ -inch bamboo sieve, and if the cinnabar is of the "red" variety the crushed ore is panned and the clean cinnabar (concentrate) removed, and the tailings treated for quicksilver in the retort furnaces.

(TO BE CONTINUED.)

### Testing Safety Devices.

TO THE EDITOR:—On page 230 of May 27th, referring to the article "Testing Safety Devices," I do not see the necessity of cutting loose the cage or skip and letting them go to the bottom of the mine. I have tested these appliances for many years and my method is as follows:

The first of each month, before the shift goes into the mine, I have the cage raised above the floor level; two pieces of timber, 8x8 inches, are placed under the cage and across the shaft, of course resting on the floor. The cage is lowered onto these and the bolt taken out of the clevis; a piece of  $\frac{1}{4}$ -inch hemp rope is tied between the bolt and the drawbar to the cage. The cage is now raised 1 or 2 feet from the floor and the hemp rope is severed with an ax.

The safety device is kept well cleaned. I use gasoline freely at this time, after the test, to cut all gum from the bearings, and then oil them a little with a good oil that will not gum. I have made this test many times and I have never had the cage drop more than 2 inches—in fact, it does not drop 1 inch. I see to the good working of the cage myself. I leave it to no one, and I want all the bearings very free.

I think the binding of the safety devices is usually due to the making of the cages, especially the working bearings, too tight. This work is often done in the factories by men of no experience in mining, and they make the fits all alike. The bearings of the cam shafts and the fit of the draw bar should be a very easy fit. No harm if they shake  $\frac{1}{8}$ -inch—in fact, I prefer them so; but I do want the best of stock in them. Another cause of these accidents is the use of oil too freely on these parts and never cleaning out the gum formed. This, together with a tight bearing, will surely send the cage to the bottom when the rope breaks.

Cages and skips get racked badly by frequent hard drops on the chairs, catching in the guides, and by side strains when handling heavy weights. If the cam shafts are a close fit, they are bound tight by such racking out of shape of the cage and are rendered useless for the service they are intended for.

The bearings of chairs should also be made a very

loose fit. They are usually made as if they were to do service as a line shaft. Such parts of machinery as are placed in damp places and at times covered with dirt, handled and taken care of by men that know practically nothing about machinery, should be easy fits. I know that some superintendents, buying machinery for a mine, think, if they see "slobbering" fits anywhere, they are getting poor machinery; but, if a firm understands the use the machinery is to be put to, they will be careful and make their fits according to the requirements.

For the rope fastenings to the cage I prefer good, heavy wrought iron clamps—four or six, according to the weight they are to carry. I want the bolts to be made of Norway iron and two nuts to each bolt. At the time I am making the test of the safety devices I tighten the nuts to the clamp bolts. It is surprising how one can turn these nuts every month, even after several years work, and when gone over every month I have found them a little loose, especially after a heavy lift, such as raising the "sinker," when a heavy one.

I think it a good plan to cut a little off of the rope every little while, if only 2 feet; at this time the clamps should be well cleaned and the bolts cleaned from all dirt and grease; use a little gasoline or coal oil and look over the threads; see they are a good fit. I want these nuts to turn all the way on with a wrench—not a fit that will allow of their being turned on with the fingers; such nuts work loose easily. Give plenty of stock in these parts. ARTHUR HENDEY.

Jerome, Ariz., June 10.

### The Extension Sluice in Dredging.

Those seeking a means of distributing tailings from dredging operations so as to leave comparatively level land in the wake of the dredger can find a means to that end in employing an extended sluice, such as is shown in the accompanying illustration. The tailings stacker handles the debris from the screens without difficulty and is said to be generally satisfactory to the managers of the numerous dredging

The Extended Sluice in Dredging.

plants; but the stackers leave unsightly piles of cobbles, which are stacked up in rows or isolated hillocks, rendering the land practically useless for a greater or less period. Undoubtedly, the gold generally obtained in dredging operations usually renders the land more valuable for mining than for any other purpose, and yet there are places where it may be not only expedient but desirable to leave the land after dredging a comparatively smooth plane, which will quickly become covered with the fine silt from neighboring rivers, deposited during the flood period. In a few years—perhaps four or five—the land is again tillable and may be once more used for agricultural purposes. The illustration shows the simplicity of the construction and operation of the extended sluice. It may be swung from side to side, and all material discharged over it is deposited so far away from dredging operations at the front end of the boat—in the larger dredgers nearly 200 feet—that there is little likelihood of the tailings interfering with the operation of the buckets.

The leveling of tailings after a dredger is largely a matter of sentiment, for the value of the land reclaimed after dredging is only a small part of the value of the gold recovered from a profitable claim; still there may be those who desire to leave their tailings dump level ground, instead of in piles of cobbles, and this device, which is attached to a dredger in New Zealand and taken from the New Zealand Mines Record, shows how this may be accomplished with comparatively small expense in capital outlay and in manipulation of the sluice.

### Reprecipitation of Gold From Cyanide Solutions and Absorption of Gold by a Wooden Vat.\*

Written by A. N. MACKAY.

The following notes may be of interest, as the writer has seen no mention of similar phenomena in any of the technical journals:

1. In the first case of reprecipitation, a vat of pyritic concentrates obtained on Wilfley tables, carrying about 30% pyrites,  $\text{FeS}_2$ , and worth about ten ounces per ton, had been put under treatment; but apparently it had been very much neglected, for it assayed eight ounces when the writer took charge, four months later.

It was decided to turn over the material for aeration purposes, and to do so a trench was cut through the concentrates from top to bottom, and samples were taken of the "faces" thus exposed for each foot of depth and assayed with the following results:

	Ozs.	Dwts.	Grs.
Sample of top foot	0	12	0
Sample of middle foot	2	8	0
Sample of bottom foot	17	8	0
Sample from top to bottom	6	2	0

This showed that the gold extracted in the upper part had been reprecipitated in the lower. Another "face" was then sampled every 6 inches in depth, giving the following results:

	Ozs.	Dwts.	Grs.
Sample of top 6 inches	0	11	0
Sample of next 6 inches	0	17	12
Sample of next 6 inches	1	0	0
Sample of next 6 inches	5	8	0
Sample of next 6 inches	16	2	0
Sample of bottom 6 inches	33	0	0
Sample from top to bottom	9	6	0

Washing the average sample with water reduced the value to 8 ozs. 8 dwts., while the sample from the bottom 6 inches was reduced in value to 30 ounces; a rough amalgamation test on the latter sample showed that the value could be brought down to 19 ounces.

This showed conclusively that the reprecipitation had taken place in the lower levels. The chief cause

seems to have been the use of a too alkaline solution with a too slow percolation rate, the excessive alkali having time to act on the pyrites forming soluble sulphides, which destroyed the cyanide and liberated the gold; probably, also, failure to keep the concentrates covered with solution allowed the formation of sulphates, which may have helped in the decomposition of the cyanide.

It may be of interest to add that by "turning over" twice and circulating a .25% solution very rapidly, the value was reduced to 15 dwts., below which it refused to go; the material was then fed into one battery box in small lots each day and sent, without concentration, to the sand vats. An increase of 3 grs.—6 grs. in some cases—in the residue values was noted in those vats into which it was sent, from which it was calculated that the pyrites had been reduced in value to between 3 dwts. and 4 dwts.

In the second case, reprecipitation took place from a .020% solution which constituted the circulating water used in the battery, etc., which, after leaving the sand separation vats, passed over spitzkasten to settle out the slime, and thence returned to the feed-water tanks. Its gold contents were 3 dwts. to 4 dwts. per ton. The slime-sludge settling in the spitzkasten was run into by the agitators and a sample of this sludge was taken very frequently—every ten minutes or so—and put into a bucket; when complete it was well mixed and a portion put through on a fil-

\*Trans. of Inst. of Min. and Met.

ter pump for assaying. As a general rule, this was done immediately the sample was ready; but, by chance on one occasion, it was allowed to stand overnight and unaccountably showed an increase from normal values. Reprecipitation was suspected, and the next also was allowed to stand, samples being taken out at regular intervals. The slime and solution being assayed, the results were:

Time.	Slime			Solution		
	Ozs.	Dwts.	Grs.	Ozs.	Dwts.	Grs.
2 P. M.	0	4	0	0	3	6
6 P. M.	0	4	18	0	2	18
10 P. M.	0	5	12	0	1	21
8 A. M.	0	7	0		Trace.	
5 P. M.	0	7	0		Trace.	

Thus it was shown that complete precipitation had taken place in about eighteen hours.

The protective alkali was about equal to .04% KOH per ton of solution, and it seems probable that this alkali had acted on the fine sulphides in the slime—about .5% FeS<sub>2</sub>—forming alkaline sulphides, which destroyed the cyanide.

This, however, could not very well take place in the agitators, as the cyanide was added while the agitators were filling; but a few test cases were made in which (1) no cyanide was added till the agitator was full; (2) agitation was stopped and no cyanide added till the agitator was full. In both cases an increase in residue values was always observed, the second case showing on an average about 3 grs. worse than the first, which was itself 6 grs. worse than normal residues.

The cyanide in the whole works was reduced considerably until the alkalinity was only .01%, at which point no reprecipitation occurred. The cyanide then in use was that showing 104% KCN and 10% KOH, under the circumstances the worst possible, for the water from the mine had an alkalinity of about .03%.

2. A wooden leaching vat, which had been used for treating by percolation the "sands" of a roasted sulpho-telluride ore, had to be dismantled when a change in the treatment was made. Some pieces of the wood were carefully cleaned and incinerated and the resulting ashes assayed, and the cocoanut matting and the Hessian used in the filter bottom were similarly treated, the values as calculated back to per ton of original being:

	Ozs.	Dwts.	Grs.
Wood	12	8	0
Hessian	3	12	0
Matting	5	14	0

The wood was a variety of red pine and had been in use about eighteen months, treating in that time about 1200 tons of an average value of 20 dwts.

The values in the matting and Hessian may be due to very fine particles of ore in them which could not be beaten out, or may have been caused either by insufficient water washing or by the use of unsuitable water, for a white incrustation found on the joints of the timber, consisting of chlorides, sulphates, carbonates, etc., of sodium, calcium and magnesium, assayed 7 ounces, the water in use carrying 10% or so of solids in much the same composition.

## THE PROSPECTOR.

The rock samples from Reno, Nev., are: No. 1, tourmaline rock. It is of no value, but it would be well to carefully prospect the vein or dike from which this rock came for cassiterite (the oxide of tin), as tinstone very commonly occurs in association with this rock. It may occur in finely disseminated grains of grayish, brownish or black color, with a bright, pearly luster. The tinstone, if present, can be readily separated from the tourmaline rock by panning. No. 2 is very much altered and difficult to determine. It has the appearance of being a quartz-bearing andesite (dacite), much altered, the feldspars having become kaolinized and somewhat silicified. No. 3 is a siliceous ironstone carrying chalcocopyrite (iron-copper sulphide), iron-copper glance, and malachite (green copper carbonate), the latter incrusting in thin scales. This is a fairly good copper ore.

The samples from Empire district, Nye county, Nev., are difficult of determination. The light-colored pieces are essentially a quartzose ore containing 2% or 3% iron sulphide. The ore may or may not carry gold and silver. This ore is very evidently the result of alteration and silicification of an eruptive rock, possibly diorite; but this is difficult to determine, as there are no characteristic minerals present. The dark-colored rock is also impregnated with iron sulphide. It is a very siliceous rock and resembles flint, but is made up of innumerable rounded grains of chalcadonic quartz in a finer groundmass, and it may be a devitrified, glassy lava, like pearlstone. Felsite sometimes presents this appearance. Both of these rocks should be assayed for precious metals.

The rock samples from Pinos Altos, N. M., are: No. 1, typical rhyolite, in which may be seen quartz, plagioclase, biotite and other distinct crystals. No. 2 is andesite. No. 3 is a sheared and much altered rock—apparently originally granitic. No. 4 is a metamorphic rock—sericite schist.

There has been received, addressed to this department, a red pasteboard box containing three sam-

ples—one is nearly black, one gray and one yellowish green. Address of sender and locality from which rock came unknown. If the sender recognizes these samples, please send in name and address.

The rock specimen from Dyer, Nev., is hematite, of the variety known as specular iron ore; the white crystals in it are feldspar.

The rock specimen from Princeton, B. C., is a feldspathic dike rock in which there has been a large development of garnets.

The rocks from Douglas, Alaska, are: No. 1, coarse-grained calcite. No. 2, fine-grained calcite (marble). No. 3, quartz, with needles of rutile accompanying and penetrating the quartz.

The rock from Randsburg, Cal., is from a granitic dike and is rather coarse aplite, consisting of quartz and feldspar, with no mica. The small, dark spots are molybdenite, the sulphide of molybdenum. This latter mineral, although valuable, occurs in too small amount in this rock to make its treatment profitable.

The rocks from Ingot, Shasta county, Cal., are: No. 1, silicified diabase. No. 2, diabase-porphyrite.

The rock from Ballarat, Cal., is anhydrite, a variety of calcium sulphate; composition, sulphur trioxide 58.8, lime 41.2.

The minerals Nos. 1 and 2 from Dillon, Mont., are: Wad, an impure, earthy, black oxide of manganese.

## Boiler Waters and Their Treatment.\*

Written by W. M. BOOTH.

During the fall of 1902 my attention was first called to boiler compounds. A white powder was submitted for analysis, which was found to contain soda ash with a little free tannic acid. It was said that this was used to soften and to remove scale from boilers. One concern with which I was connected later had a great deal of difficulty with scale in a battery of water tube boilers, as the total solids in the water they were using amounted to 35 grains per gallon, and the scale-forming solids to more than half this amount, consisting of a large quantity of sulphate of calcium. I examined the tubes and found a very compact scale about  $\frac{1}{16}$  of an inch thick, which it was impossible to remove by mechanical means. Kerosene was tried and found ineffective. A boiler compound company offered to remove this scale, but when granted every privilege was unable to do so. Indeed, many tubes were burned out while the compound was being used. This liquid was brought to me for analysis. It was black in color, dense, had an odor of caustic soda and was very alkaline. Analysis showed this to contain, mainly caustic soda in excess, logwood, tannin, sugar, sulphate of soda, and a small quantity of gum. It is needless to say that its use was prohibited. The third compound examined contained catechu, caustic soda and tan liquor. They were, of course, 75% or higher water. The examination of a number of samples since shows that three basic chemicals are known, even by unscientific men, to attack scale within the boiler itself. These are caustic soda, soda ash, and tannic acid compounds, from sumach, catechu and the exhausted bark liquor from tanneries. A great difference of opinion seems to exist in regard to correct material to use within the boiler for the purpose under discussion. One engineer of twenty years experience tells me he has used potato water with good results; another, a little molasses occasionally, while others are partial to kerosene. That the United States patent office is willing to grant special concessions for "various and sundry" improvements in relation to boiler scale removing materials can be seen from the following, letters being substituted for the patent numbers:

A.		Parts.
Glaubers salt	.....	85
Soda ash	.....	100
Calcium sulphate	.....	10
Slippery elm	.....	4
One pound to 75 H. P.		
B.		Parts.
Ground coffee	.....	40
Logwood	.....	2
Blood meal	.....	1
Salt	.....	3
Well mixed		
C.		
Catechu, soda ash, German salts, (potash, including calcium sulphate, hydrogen sodium carbonate and common salt.)		
D.		
Wool fiber.		
E.		
Digest leguminous plants with caustic alkali, strain, concentrate and add dry moss or peat.		
F.		
Saw palmetto containing roots.		
G.		Parts.
Catechu	.....	25
Molasses	.....	56
H.		Parts.
Hemlock extract	.....	270
Soda ash	.....	150
Water	.....	130
I.		Parts.
Water	.....	450
Chest oak bark	.....	
Black oak bark	.....	
Red oak bark	.....	
Burnt sugar	.....	50
Alcohol	.....	25
J.		
Powdered coal dust.		

\* The Chemical Engineer.

Remedies from the Scientific American Encyclopedia, "Incrustation of Boilers," that have been adopted with more or less success for boiler incrustation:

1. Potatoes,  $\frac{1}{50}$  weight of water, prevent adherence of scale.
2. Twelve parts salt, 2 $\frac{1}{2}$  caustic soda,  $\frac{1}{2}$  extract of oak bark,  $\frac{1}{2}$  of potash.
3. Pieces of oak wood suspended in boiler and renewed monthly, prevent deposit.
4. Two ounces muriate of ammonia in boiler twice a week prevents incrustation and decomposes scale.
5. Coating of 3 parts black lead, 18 tallow, applied hot to the inside of a boiler every few weeks, prevents scale.
6. Thirteen pounds molasses fed occasionally into an 8 H. P. boiler prevented incrustation for six months.
7. Mahogany or oak sawdust in limited quantities. The tannic acid attacks the iron and should therefore be used with caution.
8. Slippery elm bark has been used with some success.
9. Carbonate of soda.
10. Chloride of tin.
11. Spent tanners' bark.
12. Frequent blowing off.
13. Paraffin oil has been used with excellent results in locomotive boilers.
14. Marine boilers are sometimes protected from corrosion by a very thin wash of Portland cement inside.

ANTI INCRUSTATORS.—M. E. Asselin of Paris recommends the use of glycerine to prevent incrustation in steam boilers. It increases the solubility of combinations of lime, and especially of the sulphate. It forms with these combinations soluble compounds. When the quantity of lime becomes so great that it can no longer be dissolved, nor from soluble combinations, it is deposited in a gelatinous substance, which never adheres to the surface of the iron plates. The gelatinous substances thus formed are not carried with the steam into the cylinder of the engine. M. Asselin advises the employment of 1 pound of glycerine for every 300 or 400 pounds of coal burnt.

1. BOILER INCRUSTATION, TO PREVENT.—For a 5 H. P. boiler, fed with water, which contains calcic sulphate, take: Catechu, 2 pounds; dextrine, 1 pound; crystallized soda, 2 pounds; potash,  $\frac{1}{2}$  pound; cane sugar,  $\frac{1}{2}$  pound; alum,  $\frac{1}{2}$  pound; gum arabic,  $\frac{1}{2}$  pound.

2. For a boiler of the same size, fed with water which contains lime: Turmeric, 2 pounds; dextrine, 1 pound; sodium bicarbonate, 2 pounds; potash,  $\frac{1}{2}$  pound; alum,  $\frac{1}{2}$  pound; molasses,  $\frac{1}{2}$  pound.

3. For a boiler of the same size, fed with water which contains iron: Gamboge, 2 pounds; soda, 2 pounds; dextrine, 1 pound; potash,  $\frac{1}{2}$  pound; sugar,  $\frac{1}{2}$  pound; alum,  $\frac{1}{2}$  pound; gum arabic,  $\frac{1}{2}$  pound.

4. For a boiler of the same size, fed with sea water: Catechu, 2 pounds; Glauber's salt, 2 pounds; dextrine, 2 pounds; alum,  $\frac{1}{2}$  pound; gum arabic,  $\frac{1}{2}$  pound.

When these preparations are used add 1 quart of water, and in ordinary cases charge the boiler every month, but if the incrustation is very bad, charge every two weeks.

5. BOILER INCRUSTATIONS, TO PREVENT.—For boilers of 100 H. P. fed with river water, use the following, which should be renewed whenever the boiler is emptied: Crystallized soda, 18 pounds; dextrine, 18 pounds; alum, 6 pounds; sugar, 6 pounds; potash, 3 pounds.

6. For the same sized boiler, fed with sea water: Soda, 24 pounds; dextrine, 24 pounds; sugar, 12 pounds; alum, 3 pounds; potash 3 pounds.

I have no hesitancy in saying that caustic soda in large excess is injurious to boiler fittings, gaskets, valves, etc. That it is injurious in reasonable excess to the boiler tubes themselves, I have yet to prove. Foaming and priming may be caused through excess of caustic soda or soda ash, as is well known by every practical engineer. I can strenuously condemn tannic acid, and of the use of its salts, I am fearful. It may unite with the organic matter present in the form of albuminoids and with the calcium and magnesium carbonates present. That it removes scale is an assured fact, that it removes iron with the scale is also assured, as tannic acid corrodes an iron surface rapidly. Compounds of vegetable origin are widely advertised, but often contain dextrine and gum, both of which are dangerous, as they coat the tubes with a compact scale, not permitting the water to reach the iron. Molasses is acid and has no place in the boiler, and starch substances generally should be denied. I have not investigated the action of kerosene, but know that in large quantity its use must be very dangerous, as it is a very volatile oil and must soon leave the boiler and pass over and through the engine.

We now have two materials the use of which in boilers is not prohibited through action upon the metal itself or on account of price. I refer to soda ash and caustic soda. Sodium triphosphate and sodium fluoride have both been used with success, but the cost is several hundred per cent greater than soda ash. If prescribed as per analysis, in slight excess, there should be no injurious results through the use of caustic soda and soda ash. Would it not be practicable to manufacture an intimate mixture of

caustic soda and carbonate of soda, containing enough of each to soften the average water of a given vicinity?

The less scientific members of the boiler compound guild carefully consign each sample of water to the sewer and send the regular goods. Others have a stock analysis which is sent to customers of a given locality whether it contains iron, lime or magnesium sulphates or carbonates. All money, paid in excess of 3 cents per 1000 gallons, for softening water is for the privilege of using ready-made softener. Every engineer and superintendent in charge of a plant should insist that the compound used be pronounced by competent authority free from injurious materials and that it be adapted to the water in use.

Boiler compounds then should contain only such ingredients as will neutralize the scale-forming salts present. They should be used by prescription only, so many gallons per 1000 gallons of feed water. A properly proportioned mixture of soda should answer the demands of all plants depending upon this method of softening water in limestone and shale regions. It is to be remembered that a number of chemical salts, some of which suffer decomposition at the temperature and pressure of the boiler, are always found within the boiler itself, if the feed water is softened by boiler compounds. What occurs chemically, under such conditions, is a question, and salts of magnesium probably suffer considerable decomposition.

However, for small isolated plants, requiring the softening of water, boiler compounds can hardly be replaced on account of the simplicity of their action and use. Their cost should not be prohibitive, and they should render efficient service in connection with the particular style of the boiler. Steam mills, factories and small power plants, generally, often cared for by incompetent and careless engineers, require some material easily applied. For plants of from 75 to 150 H. P. 24-hour settling tanks will answer the purpose of a softening system. Two tanks, each capable of holding a day's supply and furnished above with lime and soda tanks in common, and provided with sludge valves below, may be used for this purpose. Paddles in each tank capable of thoroughly stirring the contents may be actuated from above. Large plants are operated on this principle, serving boilers of many thousand horse power. Such a system has an advantage over a continuous system, in that the exact amount of chemical solutions, required for softening the particular water in the tank, can be applied. For some variations of such a system, several companies have secured patents and are doing a large business. The fundamental principles themselves are not patentable, and have been used for many years.

For a plant with a boiler capacity of 500 H. P., a water softening system is capable of saving a great deal of money. The present tendency in connection with manufacturing concerns is to group in one battery boilers aggregating thousands of horse power. They are more easily cared for, more easily handled and render more efficient service than many isolated units. For such plants, boiler compounds and settling tanks are replaced to advantage by water-softening systems, capable of treating several thousand gallons of feed water per hour. The lime soda ash treatment has been found to be very efficient for ordinary waters. The soda ash is usually added in slight excess. It is very necessary to the engineer of such a plant to have at his right hand the services of an experienced chemist, to whom, periodically, the water should be submitted both before and after purification.

We have thus outlined the method of treatment possible of being followed by plants in most sections of the Middle States, where waters used for boiler purposes are usually hard, containing lime and magnesia, the shale sections also adding a large amount of sulphate of calcium to the water. The treatment of sea water is a special case and is beyond the scope of this paper. Waters on the Eastern coast are ordinarily very soft, as they are taken directly from rivers. In New England much of the superficial rock is of a granitic character, which produces scarcely any scale. The water of the West contains a large excess of alkali, more particularly the Southwest, and the problem of making this applicable to boiler use is as yet but partly solved. The very substances that are found in the Eastern waters at the conclusion of the softening process, that is, sulphates of soda and magnesium, are found in very large quantities; in natural waters sometimes 30 to 40 grains per gallon, and above, in the West and on the lines of the Southwestern railways. Lime is sometimes added to these waters to produce a slight scale and to prevent foaming. In the Northwest and Middle West, much of the water is highly charged with organic matter, which requires a coagulant, and several firms have been successful in removing this form of incrustation with alum compounds, principally aluminum sulphate. But our problem is particularly in connection with the waters of the Alleghany Mountain system, and I am frank to say that I consider its solution yet considerably beyond our grasp. Would it not be a profitable source of revenue to originate and maintain companies, the object of which would be to furnish softened water to the manufacturing districts of our large cities? This water could be obtained from artesian wells.

The following experiment was tried to ascertain

the action of various compounds, used for water softening, on steel.

On the first day of January I weighed into each of several tubes one gram of soft open-hearth steel of the following analysis:

	Per Cent.
Carbon .....	0.15
Phosphorus.....	0.06
Manganese.....	0.40

I was very particular to use uniform drillings and rinsed each tube several times with distilled water and finally with the liquid to be tested. To the borings in the tubes were added 15 c.c. each of the following solutions:

1. Distilled water.
2. Syracuse water, an equal amount.
3. Cortland water.
4. A solution of tannic acid.
5. A slightly alkaline solution of sodium tannate of about deci-normal strength.
6. Distilled water and mono-hydrate crystals.

Regrinding Room of the Cananea Consolidated Copper Co., Cananea, Mexico.

7. Deci-normal caustic soda.
8. Syracuse water containing lubricating oil of the following composition: 10% vegetable oleins, 90% hydrocarbons. These tubes were placed in a beaker with a piece of paper secured over the top with a rubber band, then placed upon a radiator, where they were left at a temperature of 21° C. for ten days. Upon examination the appearance of the material in each test tube was as follows:
1. Metal very badly corroded.
2. Syracuse water, an equal amount, permanently hard.
3. Cortland water, temporarily hard.
4. So badly corroded in color that filings could hardly be seen in the solution.
5. Of about the same degree of corrosion as the previous one.
6. Clear, scarcely acted upon.
7. Deci-normal NaOH, a white flocculent precipitate.
8. Medium corrosion.

These tubes were allowed to remain either on or near the radiator until February 8. The borings from the tube containing mono-hydrate crystals were removed, shaken several times in anhydrous ether, dried and weighed. The weight was found to be 1.0014 gram with a gain of 0.14%. The borings in the tube containing caustic soda were examined in a similar manner, dried and weighed. They were found to weigh 0.99965 gram, that is a loss of 0.035%. In both cases the steel had not been changed in appearance, or appreciably in weight during more than one month while in contact with the alkaline solutions, while in every other case the liquid had so corroded the drillings that the solution had become opaque.

(TO BE CONTINUED.)

PLACERS may be located in any form on the unsurveyed and unoccupied lands of the United States, but where the lands have been surveyed by the Government it is required by the statutes that placer locations shall conform to the public land surveys as closely as possible, and to

facilitate this idea the Government permits the locator to take his claim up in contiguous 10-acre tracts. This will not permit taking a claim 600x1500 feet, which is the usual size of a quartz location, but the claim may be taken 660x1320 feet, which is exactly the size of two adjoining 10-acre tracts. A square tract containing ten acres measures 660 feet on each side. So if the principal survey lines are known, that is, the section or quarter section lines, the locator may stake his placer claim with reference to these lines. In so doing great care should be given the description as referred to the land survey.

### Bryan Roller Mills in Mexico.

The accompanying interesting illustration shows one-half of the regrinding room of the concentration department of the Cananea Consolidated Copper Co. at Cananea, Mexico. In this department are eight

Bryan roller mills, all of which are doing satisfactory work. The object of employing these mills at Cananea is to recrusher certain products of concentration for the purpose of freeing the finely disseminated grains of copper sulphide which would otherwise be lost.

### The Rational Design of Head Frames for Mines.

TO THE EDITOR:—I notice in the issue of the MINING AND SCIENTIFIC PRESS of June 10, 1905, an interesting contribution on the design of head frames, by Mr. Geo. S. Binckley, and his remarks about the defective use of steel in many of these structures are undoubtedly well taken. His conclusions as to the most rational design of head frames, on the ground of economy of construction, are likewise quite correct, but similar designs have long been past the stage of mere suggestions; a number of frames built on these lines have been in operation in Europe—namely, in Germany—for many years, and I would refer you to an article by Mr. John Ross, Jr., on the equipment of the Wildman-Mahoney mines at Sutter Creek, which appeared in your paper on November 18, 1899, with cuts of a head frame designed by the writer for that company, precisely on the principle suggested by last Saturday's article. This does not by any means detract from the correctness of Mr. Binckley's remarks on the subject, and is merely mentioned as a matter of record.

A. E. CHODZKO.

THE Secretary of the Interior has made a decision concerning the school lands of Montana which will be of great value to the educational interests of that State, in declaring that the lands claimed by the State as school lands, although in the mining regions, and probably more valuable for mineral than for other purposes, may nevertheless be held by the schools unless they were actually claimed and located as mineral land by others prior to Nov. 8, 1889.

# Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 6, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINER'S LAMP.—No. 791,276; E. F. Long, Scranton, Pa.

Device of class described, comprising body having neck, collar fitted on neck of body, pintle rod having attachment portion interposed between neck and collar and clamped to former by latter, and lid hinged to body by pintle rod.

REDUCTION FURNACE.—No. 791,660; G. Walzel, Newark, N. J.

Limestone reducing furnace, comprising single stack and multiplicity of internally disposed shafts, means of communication between lower portions of shafts, single gas conveying means connected with means of communication between the shafts, charging device arranged upon top of each shaft, an independent outlet at bottom of each shaft, and emptying device connected with outlet of each shaft.

APPARATUS FOR MAGNETIC SEPARATION.—No. 791,494; C. Q. Payne, Stamford, Conn.

In magnetic separator, combination of transversely laminated separating cylinder provided with plurality of magnetizable laminae having toothed edges relatively so placed that teeth of laminae project circumferentially beyond those of adjacent laminae; means for magnetizing cylinder and for maintaining material undergoing separation in close proximity to cylinder along considerable segment thereof below its horizontal diameter and within magnetic field.

PROCESS OF EXTRACTING NICKEL FROM NICKEL-BEARING SUBSTANCES.—No. 791,090; H. A. Frasch, New York, N. Y.

Process of extracting nickel from matte containing same, consisting of pulverizing matte and exposing it to action of sulphuric acid and flowers of sulphur, and subjecting mixture to action of heat.

APPARATUS FOR OPERATING STAMP MILL DRIVES.—No. 791,732; R. Taylor, Subiaco, Western Australia, Australia.

Apparatus for operating stamp batteries, drop hammers and the like, combination of lever fulcrumed upon fixed pivot and having one end formed as double-faced cam, each of faces being described upon cylindrical curve, stamp or hammer shank to one side of which cam end of lever passes, upper tappet upon shank with which upper cam face engages, to lift shank and concurrently turn it, lower tappet at appreciable distance from upper, out of engagement with cam, against which lower cam face may strike blow when lever is rapidly driven, means for vibrating lever, and renewable linings for tappets.

CONCENTRATOR ATTACHMENT.—No. 791,711; F. S. Morgan, Nevada City, Cal.

Combination with endless traveling concentrator belt and oscillating frame thereof, of standards fixed to and rising above frame, amalgamated plate supported upon standards and inclined downwardly toward head end of belt, sluice leading from feeder and inclined toward higher end of plate, sluice being fixed relative to plate and frame, distributing box at higher end of plate and into which sluice discharges, distributor box at lower end of plate into which plate delivers, narrow trough fixed in second-named box adapted to separate free gold and amalgam and deliver lighter pulp and sulphurets over its edge into box, and fixed pendent support having points positioned in trough to agitate contents during oscillations of frame and plate.

PROCESS OF SMELTING ORE.—No. 791,577; E. Rivoll, Los Angeles, Cal.

Process of smelting metalliferous rock, which consists of establishing zone in suitable furnace in which flames of imperfect combustion are projected from burner supplied with fluid fuel, and establishing another zone in which flames of perfect combustion are projected which produce smelting heat, and moving ore through zones whereby in first zone car-

bon is deposited on ore and whereby in second zone ore is smelted and gases arising in second zone are passed through ore in first zone whereby ore is deoxidized in first zone before it passes to smelting zone.

DREDGER BUCKET.—No. 791,700; J. J. King, San Francisco, Cal.

Dredging bucket having segmental shell open at front, convergent toward rear and bent to form integral tail piece and closure at rear end, plate flanged and riveted to form closure for open sides of shell, plate having upwardly turned flange riveted to coincident edge of tail piece and side flanges bent downwardly and forming frog.

ROLLER-BEARING MULLER FOR HUNTINGTON MILLS.—No. 791,680; H. Eggers, Denver, Colo.

In muller for Huntington mills, combination with driving shaft having bracket secured upon upper end, of vertically disposed sleeve having trunnions near upper end, which are supported by bracket, shaft in sleeve which depends from bearings in upper end thereof, and extends beyond lower end thereof; tapered roller head on lower end of shaft; wooden packing ring of like taper on roller head, and tapered steel ring on packing ring; bracket extending from side of sleeve, vertically disposed coiled spring interposed between bracket and bracket on top of driving shaft, and means for varying tension of spring.

ORE BRIQUET.—No. 791,799; W. A. Koneman, Chicago, Ill.

Ore briquets for blast furnace treatment, composed of properly proportioned ore fines, finely divided uncoked bituminous coal and finely divided anthracite coal intimately mixed together, and binding agent mechanically uniting mixed particles of ore and coking and non-coking carbons and holding ore fines and non-coking particles until fines and particles are held by particles coked in initial combustion in blast furnace.

APPARATUS FOR CIRCULATING AND MIXING CRUSHED ORE.—No. 791,872; F. C. Brown, Komata, New Zealand.

Apparatus of character described, comprising tank adapted to receive material to be treated, centrally arranged material-conducting pipe suspended therein and terminating at point removed from bottom thereof, means arranged in operative relation with respect to pipe and adapted to supply medium for forcing material up through and out of pipe and into tank, and fluid supply pipe opening into conducting pipe.

## Discovery and Development of the Homestake Mines of South Dakota.

Written for the MINING AND SCIENTIFIC PRESS.

Gold was known to exist in the Black Hills of Dakota as early, at least, as 1868, and this fact is mentioned in one of the early Hayden reports. That gold was to be found in the Hills was probably known to the traders who came in contact with the Sioux, long before the date mentioned, is almost certain. It was said by the Indians that Father De Smet, a Jesuit priest, who made his home among them, cautioned them against showing the gold to white men, or even mentioning its presence. In 1874 a halfbreed Indian took some placer gold in quills to an Indian agency and described the locality in which he found it as being in the eastern foothills of the Black Hills. In 1875 began the movement of prospectors into the

efforts met with small reward, but in searching for a straying horse the party came into Deadwood gulch, at the mouth of what was afterwards called Slaughter House gulch, about half way between Deadwood and Central City. Camping on a bar at the side of the canyon, some of the men commenced at once the work of prospecting, while others attended to the duties of the camp. In a short time the discovery of a "color" was announced—a little nugget of gold worth about 50 cents, together with some fine specks of gold. Other colors were found by the prospectors and the indications were that the party had found pay gravel. This claim, known as the Wheeler Boys' mine, produced over \$100,000 during the summer of 1876, and was worked and reworked by others for two or three years thereafter.

The news of the strike on Deadwood gulch—so named because of the large amount of dead pine timber over the surrounding hills—spread quickly and in a few weeks there were hundreds of men working along the stream, and this number was soon there-

In the upper part of the gulch the canyon opened out somewhat. The hills, though not less high, were not so steep, and here a townsite was laid out and called Washington. Shortly after this a second townsite was located, adjoining Washington, which was called Golden.

Naturally, some of the more thoughtful prospectors began to search for the source of all the placer gold being taken from the surrounding gulches, and their quest led to the discovery of the Homestake mine by the Manuel brothers in 1876. The discovery was made on the north side of Gold Run, some distance from the stream, and amid brush and fallen timber. Wherever the rock was exposed it showed a dull red color. Every piece of rock taken from the surface, when crushed, gave a prospect of gold in the pan. Other claims were staked in the vicinity, among them the Highland, Palmetto, American Flag, Clara, Homestake No. 2, Big Missouri, Giant and Old Abe. All of these claims have since become famous.

In Deadwood gulch active prospecting had been

A Portion of Lead, S. D., Showing Homestake Mine.

Hills, which, after the discovery of Deadwood gulch, was swelled in 1876 to a stampede of tremendous proportions. It is stated that no less than 40,000 people of both sexes, of all ages, nationalities and conditions in life, rushed to the newest gold field. The first gold discovered by the white men of this rush was in Custer county, on French creek. Gold was found, it is true, but not in large amount. The prospectors scattered throughout the Hills. Every gulch, canyon and ravine was visited and thousands of pits were sunk in the southern Hills. Some gulches were prospected and declared worthless by the first comers, which afterward were worked with success by those coming later, and who were more thorough in their work. All the men going into the Hills at this time were not "tenderfeet." Many were from older mining camps. Colorado, Nevada and Utah furnished large delegations, and Montana particularly was well represented. One party in particular, known as the Gordon party, composed chiefly of Montana men, dissatisfied with the meager prospects on French and Spring creeks and in the numerous dry gulches, pushed northward through a wilderness of hills and canyons, in a hostile Indian country, searching for better pay. For a week or more their

after swelled to thousands. The prospectors pushed out into the neighboring gulches in every direction. Gold was found in nearly every gulch in the vicinity. Whitewood creek joins Deadwood in what is now the city of Deadwood, and the Whitewood was found payable for about 3 miles above town. There entered from the south a narrow canyon called Gold Run. This gulch was one of the richest ever found in the Black Hills. Several hundred thousand dollars were washed from it, though only a little over a mile in length. Gold Run was discovered in February, 1876. The news of the rich discoveries on Deadwood, Gold Run, Bobtail and Blacktail gulches reached Custer City—a town of 1400 houses and over 8000 people—in March following. In less than a month the entire population left Custer for the north, leaving but a score of people in the first metropolis the Hills ever knew.

Upon the discovery of a payable placer field the first thing to be done, after staking claims, is to establish a town. In this instance Deadwood became the principal city. In Gold Run the lower end of the canyon was too narrow and the sidehills too steep to admit the laying out of a town. Fallen timber obstructed travel for everything except pedestrians.

going on and lode claims were located by the score. Among these were some mines which later became noted. The Father De Smet was the most prominent. In Bobtail gulch the Deadwood mine and Golden Terra were quickly recognized as belonging to the Homestake system, lying between the De Smet group on the north and the Homestake group on the south. The Caledonia, in a tributary of Bobtail gulch, also soon came into prominence. It is a curious fact that all of these mines, which in this remarkable district have been worked with large profit, were early recognized as mines possessing great merit. There have been no surprises in this regard—that is to say, no mine of this vicinity which in the early days was considered of little value has since proved to be a bonanza. In Blacktail gulch rich conglomerate mines were located and worked. The Alpha conglomerate mine, on the divide between Deadwood gulch and Bobtail, was the first mine in the Hills to be equipped with a mill.

In those early days, although the prospects of the mines of this belt were persistent enough, and gold could be obtained without trouble from almost any piece of rock one tested, the grade of the ore was so low that few who gave the matter serious attention

believed the mines could be operated profitably for many years to come—"too low grade" was the verdict of miners generally, and also of some who were recognized as expert and with large experience. There is little wonder at this when the conditions were considered. The district was in the heart of a hostile Indian country; it was about 300 miles to the railroad at Sydney, Neb., or Cheyenne, Wyo.; labor and supplies were high, and the deposits were, at that time, an anomaly. They did not appear to be veins, and many did not hesitate to express the opinion that they would not go down. The walls were often poorly defined and uncertain, slate was as likely to be as good ore as quartz, and the experience of the past seemed to count for nothing. Notwithstanding all of these drawbacks, the work of development on the numerous claims proceeded as rapidly as the means at hand and conditions would admit, and in the summer of 1876 several transfers of lode claims were made. Mining methods were crude in the extreme. Each claim was worked independently, there was no system of development, nor of anything else.

The rich streaks were followed and the mines worked by tributaries, with little regard to future consequences. Small quartz mills were brought in and set up, some to work the conglomerate deposits on Deadwood and Blacktail gulches, others to crush the quartz from the lode claims. There were a dozen mills in Central City, mostly crushing "cement" rock, in the latter part of 1877, and half as many in Poorman gulch and Lead City, as the towns of Washington and Golden were now called—and these latter mills were working on both "cement" rock and quartz from the lodes. The first mill on the Homestake was a 35-stamp custom mill. This mill was in marked contrast to the great mills since built by the Homestake Co., and nothing, perhaps, shows more effectually the evolution in methods than a comparison between this mill and a modern Homestake mill.

This mill was equipped with thirty-five stamps, each weighing about 700 pounds, and amalgamating was done on short raw copper plates. The ore was delivered at the back of the mill by wagons holding about four tons of quartz each. It was dumped onto a platform of planks and shoveled over a partition about 5 feet high onto the feeder floor of the mill. There were no automatic feeders in those days, and all the pieces of ore too large to pass through the feed slot, at the back of the mortar, had to be broken up with hammers. The feeding was done with shovels, one man attending to ten stamps each shift of twelve hours. If he got behind with his work for a time he was given assistance, but usually some of the stamps were hung up for brief periods, while waiting for ore, which was not always assured by wagon delivery. There were no concentrators in this mill, nor in any other of the early mills built in the Hills. This mill was a fair sample of the mills at first built in the Black Hills, though few of them had more than twenty stamps and some but ten. The first large mill was the Homestake, and contained eighty stamps of 900 pounds each. This mill was built in the summer of 1878, and was shipped from San Francisco, Cal., at a cost of 6 cents per pound for freight, as all the heavy machinery was hauled from Cheyenne, Wyo., by bull teams. The mill cost \$140,000. It has since been enlarged to 200 stamps.

In these early days, as previously stated, the leasing system was introduced and the leasers had their ore hauled to custom mills for crushing. As a natural result, where these large ore bodies of low-grade rock with streaks of better pay were found, the leaser naturally followed the best pay, unless restricted by the terms of his contract. The mines were soon honey-combed by a network of irregular holes, made without system, or object, other than to get out rich ore as quickly as possible. Drifts were run into the hillside on the veins and underground stopes opened up. In some instances open cuts were made and large amounts of ore mined in this way. As a result of these slipshod and unmethodical methods, disastrous caves occurred. The California company, as the Homestake company was at first called, introduced the Nevada square-set method of timbering and this for a time lessened the dangers and losses due to caving ground. This system, however, has its limitations, and stopes can only be excavated with safety by stoping in sections, and filling the excavation contemporaneously with waste, or by stoping the ore, and drawing off only such amount as will afford the miners working room.

In the summer of 1878 the Homestake company commenced to work the Homestake mine by open cut system. A long drift had been driven into the hill and a raise put up to the surface. This raise was enlarged at the top and the cut grew rapidly in size, and later stopes were opened underground from two shafts sunk near the hanging wall of the main Homestake vein. These levels were connected with the surface by means of raises, and chutes were built on the levels below, and stoping by means of surface work became an important feature of mining on this great lode. In the spring of 1879 the first 120-stamp mill was built, to be followed soon after by a second mill of the same size. The Homestake company began to increase its holdings of mining property by the purchase of surrounding claims.

Mining operations were conducted on an increasingly larger scale. The great mills—at that time

the largest in the world—were beginning to make a record for production, and the Homestake, as everything on the north side of Gold Run was commonly called, began to be spoken of as one of the greatest mines in the world.

Water was required in ever increasing quantity to keep pace with the repeated expansions of mining operations, and water was developed in streams miles away from the mines and conducted by pipes, flumes and ditches to Lead City. Still all the water available was insufficient, and settling reservoirs were constructed in Gold Run, and the clear water pumped back for reuse. The large and constantly increasing demand for timber and cordwood resulted in the construction of a narrow-gauge railway, which eventually was over 60 miles in length, including its numerous branches and spurs. This road was built into the timber belt south of Lead City. The surrounding hills for miles have been denuded of the accessible timber. During summer the railroad hauled timber and cordwood for the entire year. Cordwood accumulated at the various hoists and mills, in vast quantity. Between the Homestake 80-stamp mill and the 120-stamp mill it was customary to pile up 8000 cords of 4-foot pine wood for winter's supply. It was delivered at the head of a chute, down which the sticks slid, piling up in a great mound nearly as large as the big mill itself. The railroad also delivered wood to adjoining properties at Terraville.

In the timber sheds gang saws cut the timbers and framers quickly prepared them for the square-set system which had been extensively adopted in all of the big mines. These timbers were seldom less than 12 inches square and from that up to 24 inches. The timbering was done by expert Comstockers, or by men who had learned the business from them. These stopes were often 100 to 150 feet long, 100 feet wide and carried up usually eight to ten floors each 8 feet high. Not only was this the practice in the Homestake mines, but in the Highland, Golden Terra, Deadwood, Father De Smet and Caledonia. Old timers on the Homestake belt will remember with distinctness the caves in the Highland, De Smet, Golden Terra and Caledonia. These caves were due in each case to the stoping of too large areas while depending wholly on the timbers for support. Here, as elsewhere, this support proved insufficient, but the caves never occurred without warning. For days and sometimes for months the settling of the ground, the splintering and shifting of the timbers, the crushing of joints, and the fall underground of small rocks gave abundant warning of the approaching collapse. And yet there was at hand an inexpensive and safe remedy for this condition.

The ore bodies of this district occur in pre-Cambrian schists, which have been intruded by large dikes of felsite. The schists are overlaid by the quartzites, sandstones and limestones of the Cambrian, with conglomerate at the base, and where not eroded, by later formations. The intrusive dike rock had penetrated into the overlying sedimentary beds, lifting them in a dome-shaped mass, and thrusting sheets of felsite between the strata of these Cambrian rocks, forming a typical laccolith. In the vicinity of Lead City these sheets of intrusive rock were from 5 to 10 feet, and in places 200 feet or more in thickness. In some instances the sheet lay directly on the ore, in others the conglomerates rested on the schists.

Above the Homestake vein and on the hanging wall side was one of the largest of these masses of intrusive rock, although the vein itself was uncovered by erosion. At the Highland a sheet of felsite covered the vein and so also did it at the Deadwood. At the latter mine thousands of tons of this "porphyry," as it was called, were stripped from the vein, in order that the ore might be safely removed. At the Highland the ore was stoped up nearly to the felsite when the mass caved and destroyed a stope. At all of these mines this waste, which became such an annoyance and source of expense, could have been utilized to good advantage in filling the underground stopes, but mining science had not, at that time, progressed to that point in the Black Hills, although this is the common practice to-day.

At the Caledonia a crosscut tunnel was run into the hill 800 feet to the ore body. The usual open cut at the surface was made, connecting with a stope above the tunnel level. The tunnel reached the vein 200 feet from the surface—the dip of the schists of this region is from 45° to 65°, and sometimes steeper. A shaft was sunk at the end of the Caledonia tunnel, in about the middle of the vein. This shaft reached the foot wall of the main or hanging wall vein, about 100 feet below the tunnel level. A large stope was opened on this level, called the 300. Around the shaft was left a pillar of ore about 30 feet square. The vein measured horizontally was here 195 feet wide. The stope was heavily timbered, but the weight of the superincumbent ore, resting on a talcose foot wall, resulted in collapse and the hoisting machinery went down with the cave. This accident, which might have been avoided by running in porphyry filling from the surface, cost the Caledonia company many thousands of dollars and for a time completely suspended all operations, except those of recovery of the lost workings.

The methods of working were continued along practically the same lines for years, the process of

evolution being slow, but as time went on experiments were made and radical changes were introduced, until to-day there are no mines of the Homestake belt being worked by the same systems as those followed for the first ten years of mining in the Black Hills.

All of the mills after the Homestake 80, large and small, were equipped with rock breakers and raw copper plates. Concentrators were tried at one time in one of the Homestake mills, but, proving unsatisfactory, their use was discontinued, and instead, what were known as "blanket houses" were built. There were two of these on Gold Run below the mills. They were provided with a series of shallow sluices each about 22 inches in width. In these sluices were laid long strips of Brussels carpet, over which the tailings were run. These carpet sluices caught a large amount of concentrates, consisting chiefly of partly oxidized pyrite, iron from stamps and mortars, and coarse sand. The carpets were washed from time to time (three or four times daily) in tanks of water at the lower end of the buildings, which were about 300 feet in length. Several thousand tons of this low-grade material were saved in heaps outside the buildings and afterward sold to the Deadwood and Delaware smelter.

There was little specimen rock in these mines, though occasionally there were found handsome pieces of gold-bearing ore. Generally the rock ran \$4 to \$5 per ton in the upper levels, but this value decreased somewhat with depth, though the great increase in the size of the ore bodies in depth more than compensated for the falling off in value. There were through all of these mines streaks or zones of higher grade ore, but these were no longer followed, leaving the poor ore standing, as was the case under the leasing system. The rich ore was broken in proper proportion to insure as regular a monthly output as possible, and this has always been a notable feature of the Homestake—uniform output—and this company has never missed a dividend. The development work has always been kept well in advance of stoping operations, and the entire vast holdings and equipment of the property has been paid for by the mines. The original call was for \$200,000, and since that was paid in, early in 1878, the mine has been not only self sustaining, but has spent millions of dollars in betterments, and paid millions more in dividends. The production has been nearly \$80,000,000.

In time the Homestake company, the first to extensively operate on the lode, absorbed the Highland, the previously consolidated Deadwood-Terra, the De Smet, Caledonia and other mines of the group, until it now owns practically all of the territory extending from Deadwood gulch southward for 6000 feet or more with a width of 2000. All of this territory is not ore, but there are so many and such large ore bodies that the amount of ore available is estimated by the millions of tons. There are on the consolidated properties six stamp mills, having a total of 1000 heavy stamps, each of which crushes over four tons of ore daily, or about 1,500,000 tons annually. There are mines making some pretension to greatness that have not 4000 tons of pay rock in sight, and but few can show enough ore to keep this aggregation of stamps employed for a year. Below the 800 level and extending below the 1200 level it is known that the main ore shoot of the Homestake mine is from 400 to more than 500 feet wide.

The amount of ore required by these great mills demands much resourcefulness on the part of the management, and there must be ample facilities to handle the immense tonnage. There are six shafts, all well equipped, the principal one being the Ellison, which has three compartments, two of which are equipped with double-deck cages, the third being for air pipes, water column, etc. This shaft has cost \$500,000 and is equipped to go to 3000 feet.

The compressors have abundant capacity to supply 250 rock drills, and one is used to supply motive power to underground motors and to motors on the surface tramway which runs from the Ellison shaft to the mills. The cars are hauled in trains of twenty-eight steel 4-ton cars, over a steel trestle which at one place is 100 feet high. From the Old Brig shaft, ore is delivered to a mill by aerial tramway, and from the Golden Gate, the ore is sent to mill by a Robins belt conveyor.

(TO BE CONTINUED.)

**Goldfield District, Nevada.**

The most interesting mining region in the western United States to-day—that is, the one which is at present attracting the greatest amount of attention,

Geological Survey. It is the latest and most complete description of the Goldfield region thus far published:

DEVELOPMENT.—The new camp of Goldfield, in Nevada, was revisited by the writer in November of this year (1904). This district lies 23½ miles south of

February, 1904, however, rich finds began to be made in certain spots south of Columbia mountain. Now there are probably upward of 6000 inhabitants in the district. The town of Goldfield and a number of adjacent smaller camps have sprung up. It is estimated that \$2,000,000 worth of ore had been shipped up to

Columbia Mountain and Mine to the Right, Showing Strata of Porphyry and Limestone Tilted up by the Granite.

The January Gold Mine, Goldfield District, Nevada.

The Black Butte and Quartzite at Diamondfield, Goldfield District, Nevada

is that about Goldfield, in southwestern Nevada. This district was discovered in the latter part of 1903, and was at first called the Grandpa district. This was later changed to Goldfield. The following description of the geology of the district is by J. E. Spurr, and is from Bulletin 260 of the United States

Tonopah (about 28 miles by wagon road), and was located late in the spring of 1903. At the time of the writer's first visit, shortly after its location, the only work being done was by a few men on what is now known as Columbia mountain. Up to that time no good strikes had been made. About January and

November, 1904; since then the amount has been largely increased.

CONDITIONS.—Goldfield is reached by stage from Tonopah, to which point a railroad runs, connecting with the Carson & Colorado Railroad at Rhodes; a branch is now under construction to Goldfield. The

camp has a water supply which is said to be sufficient, but in all other respects—fuel, climate, supplies, etc.—it partakes of the inevitable disadvantages of the desert.

**GENERAL GEOLOGICAL SITUATION.**—The district is bounded on the west in part by a lava-capped mesa (the capping lava is reported to be basalt. A brown sandy-looking rock underneath this, a specimen of which was sent to the Survey by Mr. Maynard Bixby, is a rhyolitic glass flow), whose erosion has laid bare the underlying gold-bearing rocks. The auriferous region is characterized by numerous low, irregular ridges standing out from the lower and more nearly level surface. These ridges owe their origin to hard reefs of quartz which form their crests, whose resistance to erosion has left them thus protruding above the general elevation; and in these quartz reefs the auriferous deposits are found.

**COLUMBIA MOUNTAIN.**—Columbia mountain is the most prominent of the ridges, and some notes on its geology were made public by the writer last year in notes on the geology of the Goldfield district, Nev., Bulletin United States Geological Survey No. 225, pages 118–119. Near the south end of the ridge the rock is largely alaskite (an igneous rock consisting of quartz and feldspar), which is sometimes of granitic structure and sometimes very fine grained, even resembling quartzite. White mica or muscovite is sometimes present, and pure quartz veins or dikes of similar origin also occur. These alaskitic rocks are intrusive into a dark siliceous rock (jasperoid), which is probably the result of the silicification of an original limestone. We may believe this limestone to have been Paleozoic, and the alaskite is certainly

pah. The rhyolite resembles the rhyolite of the Gold Mountain district, which lies about 4 miles south of Tonopah, on the road between Tonopah and Goldfield, and this Gold mountain rhyolite again resembles closely some of the phases of the earlier (dacitic) rhyolite at Tonopah. The relative ages of the rocks at Goldfield have not been determined, but it may be that they are like similar rocks at Tonopah.

**PERIOD OF MINERALIZATION.**—At Goldfield the ores occur in both rhyolite and andesite, showing that the mineralization occurred subsequent to the eruption of both lavas. At Gold mountain the ores evidently were formed after the eruption of the rhyolite, and at Tonopah the eruption of the earlier (dacitic) rhyolite was followed by a period of mineralization which produced veins showing frequently a larger proportion of gold than the locally more important veins whose formation followed the eruption of the earlier andesite. There is, therefore, the possibility that the Goldfield deposits are identical in origin with the later series of veins at Tonopah. Indeed, there are at Tonopah, in one place at least, mineralized quartz reefs in rhyolite tuffs which have the same peculiar characteristics as those of the Goldfield reefs, and these Tonopah deposits have afforded moderate assays showing gold and no silver.

**NATURE AND ORIGIN OF THE ORE DEPOSITS.**—The veins at Goldfield are not persistent nor well defined. The outcrop of the quartz bodies are irregular, straggling, branching and apt to disappear suddenly (Fig. 1). Neither were any definite systems observed, though further study might detect them. The outcrops may even be nearly circular or crescentic, and frequently they are roughly lenticular and

been extracted. It is then seen to have a definite channel-like shape, often more regular than that of the whole outcropping reef, though it has usually a limited extent in the direction of its greatest elongation (Fig. 2). It seems that these pay shoots represent the main channels of hot water circulation, while the siliceous casings are the result of the water soaking through the rock adjacent.

**VALUE OF ORES.**—The ores are often of very high grade. As an extreme example may be noted a shipment of fourteen and one-half tons from the Sandstorm (Kendall claim), which, when worked in a stamp mill, yielded \$45,783 net, while the tailings still contained about \$1000 to the ton. From the McKane-Bowes lease on the Jumbo there was taken out in five months, from a space 100 feet long and 200 feet deep on the shoot, \$600,000. One small shipment from this lease—917 pounds of ore—gave gross returns of \$4766. The whole production of the camp has been from ore which may be roughly estimated as averaging \$200 to \$300 per ton or more. The values are generally all in gold; silver is usually practically absent, though the shipping ore from the Combination mine contains from one to three ounces.

**DEPOSITION OF RICH ORE DURING OXIDATION.**—The origin of this rich ore is important to consider in order to judge the future chances of the district. Most of that which has been extracted up to the present time has been oxidized ore. The ores are mixed sulphides (usually in large part pyrite) and oxides up to near the surface. The oxidized material which follows cracks and seams is usually found to be several times (sometimes several hundred times) as rich as the unoxidized portion. The irregular spongy

The Simmerone Mine, Goldfield District, Nevada.

pre-Tertiary. On the north end of the mountain the rock is a very much altered rhyolite, in which are broad masses of white to purplish and reddish cherty quartz, extending irregularly in a northern direction. This quartz is simply a highly silicified rhyolite. The silicified areas have ill-defined walls, and the highly mineralized portions which they inclose are very irregular.

**PRODUCTIVE AREA.**—The area of known ore bodies has, since last year, spread far out from Columbia mountain, so that now it may be estimated at about 6 miles square. The most productive area is inclosed in a square 2 or 2½ miles in either direction. The chief mines at the present time are the Jumbo, the Combination, the Florence and the January, all grouped together about a mile south of the southeast end of Columbia mountain. About 5 miles southeast of the Columbia mountain is the Diamondfield group, including the Vernal, the Quartzite and the Black Butte. Shipments have also been made from this group. Other ore deposits have been developed in various parts of the field.

**NATURE OF ROCKS.**—The rocks in that part of the field examined during this last trip (the region of Columbia mountain, Diamondfield, and the Jumbo group of mines) were found to be almost entirely volcanic, consisting of rhyolite, rhyolite tuffs, andesite and basalt, all probably of Tertiary age. The alaskite and jasperoid of Columbia mountain are hardly represented in the surrounding district. In a press bulletin, given out earlier, the rock constituting the ore at the Tonopah Club mine was characterized as probably jasperoid (silicified shaly limestone). The specimen collected, however, proves upon microscopic examination to be a somewhat disintegrated glassy volcanic rock. The predominant rocks are abundant rhyolites and andesites, while basalt is rare. One andesite from near the Tonopah Club, examined microscopically, is a hornblende-andesite, resembling the earlier andesite at Tonopah. A patch of basalt from near the Florence is an augite basalt, like the basalt of Siebert mountain at Tono-

intermittent. The quartz itself is gray and jaspery, and is due almost entirely to the silicification of the volcanic rock in which it occurs. Practically no ordinary vein quartz was observed.

Indications show that this silicification (and the accompanying mineralization) is the work of hot springs, and that these irregular reefs represent the horizontal sections of columns of rocks traversed by rising columns of hot water. Had the rocks been strongly fractured we should have had veins like those of the early andesite at Tonopah, which are also due to hot-spring action; but at Goldfield the lack of such a fracture system resulted in this curious and rather unusual type of deposit. It follows that the quartz bodies will probably, as a rule, extend deeper vertically than horizontally, and so have roughly the nature of columns or pipes.

**PAY SHOOTS.**—The greater part of one of these jaspery quartz reefs, although showing disseminated pyrite, contains little or no values in gold. Microscopic investigation has shown that in such quartz the pyrite is often probably mainly indigenous—that is, that the iron sulphide has been formed by the action of the sulphur contained in the hot spring waters upon the iron silicates contained in the hornblende and biotite. This explains the absence of gold, the pyrite having the same origin as the barren pyrite near the ore bodies in the country rock at Tonopah. Within some of these barren reefs of silicified volcanic rock at Goldfield, however, prospecting has led to the discovery of portions containing gold, sometimes in large quantities. Such portions are apt to be lenticular or irregular, like the main quartz reefs, and they are not easily distinguishable from the barren quartz except by panning or assaying; but these shoots are the real ore deposits, and the mass of the reefs constitutes merely a siliceous jacket or casing, such as is known to surround ore bodies in some other parts of the world. While the siliceous casing may be 25 or 30 feet wide the auriferous portion may be only 1 or 2 feet, and the form and extent of this portion become evident only after the ore has

nature of the free gold particles in such oxidized material completes the proof that this is gold that has been dissolved and redeposited in concentrated form during the process of oxidation. Iron sulphate derived from oxidation of the pyrites is the probable agent. A peculiar yellow coating, pointed out to the writer as the best sign of values in the oxidized ores, was shown by Dr. Hillebrand to be a basic ferric-alkali sulphate, containing both sodium and potassium—perhaps jarosite. Other sulphates, such as alum and gypsum, are abundant. These oxidized ores are prepared for shipment by screening, the fines being shipped and the coarse quartz rejected. This is a rather crude method of treatment. Some specimens of ore from the waste or low-grade dumps have been found by the writer to show under the microscope a large amount of free gold.

**RICH SULPHIDE AND TELLURIDE ORE.**—As the ground-water level at Goldfield is usually high for this desert country, water having been encountered in several shafts at from 150 to 200 feet, it is plain that this oxidized ore is only a temporary supply. In the Combination and Florence mines, however, sulphide ores of very high grade have been encountered below the oxidized zone. In these mines a dark-gray copper-bearing mineral is most intimately connected with the gold, being very rich. A specimen from the Combination, analyzed by Dr. Hillebrand, proves to be a sulpho salt of copper, antimony and arsenic, which, so far as qualitative composition goes, may be tetrahedrite. Tellurium is also present in this ore; and the same element has been reported elsewhere in the district. Therefore the sulphide ores may also be very rich. Moreover, while the difference between the oxidized and unoxidized portions of the ores within the oxidized zone is in general so great, certain shoots occur in the oxidized zone, as in the January and the Jumbo, where the unoxidized quartz is of extremely high grade. Such ore appears to contain mostly pyrite as metallic mineral, but in view of the fact that tellurium is known to be present in the district, it is probable that gold telluride is present.

Dr. Hillebrand has determined tellurium and gold (probably gold telluride) as well as a copper mineral in a specimen of ore of this class from the January mine. These are probably residual minerals similar to those characteristic of the unoxidized zone, as microscopic work by the writer indicates. Most of the hard quartz in the pay shoots of the different mines shows, when thus examined, pyrite, tetrahydrite (?) and free gold, the last two closely associated and often intergrown. The tellurides have not yet

sult of descending or ascending waters. Concerning this the evidence is not conclusive; but there is no sufficient evidence that these rich ores have been concentrated from the lean antecedent quartz mass, and the presence of elements like arsenic, antimony and tellurium in the subsequent sulphide ore suggests a deep-seated origin. Moreover, microscopic examination of such rich ores shows they have as gangue cherty silica like that of the first period of silicification, and the associated evidence favors the idea that

not unfavorable to the continuance of ores of high grade, or at least of good grade, down to considerable depths. There is, however, as already demonstrated by exploitation, no continuous regularity to the ore shoots, whether sulphide or oxidized. They are curving, irregular and often lenticular, but it may happen that below a shoot which has come to an end another shoot may be found occupying a slightly different relative position, or even overlapping the first.

The engravings accompanying this article are furnished through the courtesy of Mr. John D. Hoff of San Francisco, Cal.

Vagaries of Ore Deposition at Goldfield, Nevada.

Type of Vein Formation at Goldfield, Nevada.

been identified microscopically, probably because of the difficulty of distinguishing them from pyrite.

It appears, then, that the rich oxidized ores owe their richness, not primarily to concentration during oxidation (though this process has certainly been very important), but to the existence of shoots of rich antecedent (sulphide) ore.

**PROBABILITY OF RICH ORE IN DEPTH.**—Concerning the origin of these rich sulphide ores, it is probable that some, so far as can be yet seen, are purely primary, while evidence points out other cases as having been formed subsequent to the main silicification of the reef, as in the Combination mine. Here the rich auriferous sulphides have formed in a broken zone (breccia zone) in the silicified barren reef, and occur as seams and often as coatings on the pebbles in the breccia. The question arises, however, as to whether this subsequent mineralization was the re-

sult of descending or ascending waters. Concerning this the evidence is not conclusive; but there is no sufficient evidence that these rich ores have been concentrated from the lean antecedent quartz mass, and the presence of elements like arsenic, antimony and tellurium in the subsequent sulphide ore suggests a deep-seated origin. Moreover, microscopic examination of such rich ores shows they have as gangue cherty silica like that of the first period of silicification, and the associated evidence favors the idea that

the conditions of this subsequent deposition were very much like those of the first. Besides the elements mentioned above, bismuth occurs in the ore. In the January mine it occurs in the oxidized ores in the form of silvery scales, which is, as described by Dr. Hillebrand, bismuth; perhaps the oxide bismite. In the Combination long needle-like crystals have been found, which, according to the manager, Mr. Collins, give the chemical tests for bismuth sulphide (bismuthinite). In the January mine the silvery mineral above noted is sometimes arranged in long rod-like forms, and these are very likely pseudomorphs after the sulphide. This silvery mineral is usually, but not always, an indication of rich ore in the January. According to Mr. Hamilton, several of the Blue Bull samples show bismuth. Barite is a common mineral in all these deposits, but is not abundant. The indications are, therefore,

## Personal.

H. A. PRINGLE has returned to England from Rhodesia.

A. B. FRENZEL of Denver, Colo., has been in New York City.

H. E. WOOD has returned from New York City to Denver, Colo.

C. W. PURINGTON has been examining mines at Eureka, Colo.

CHAS. TAYLOR is superintendent El Oro mine at Poza, Sonora, Mexico.

A. E. HUMPHREY has returned to Butte, Montana, from Salt Lake City, Utah.

R. C. GEMMEL of Salt Lake City, Utah, is examining mines in Zacatecas, Mexico.

SAMUEL NEWHOUSE has returned to Salt Lake City, Utah, from an Eastern trip.

J. W. CRAIG is manager Tudor G. M. Co., Ltd., at Luipaard's Vlei, South Africa.

R. HOPKINS has charge of work at the California mine, near Silver City, Idaho.

N. TRELOAR has been made general superintendent Yampa mines at Bingham, Utah.

T. JAY has resigned as foreman Jumho mine, Hump, Idaho, being succeeded by N. McGree.

W. E. MILLER, secretary of the Arizona C. Co., has left Morenci, Ariz., for his home in Scotland.

O. B. WARD has been appointed metallurgist to the Sons of Gwalia, Leonora, Western Australia.

E. GRIBBEN has been appointed manager Durham Consols mine at Etheridge, Queensland, Australia.

O. Will of Salt Lake City, Utah, has taken charge of work on a silver-lead property near Hailey, Idaho.

C. H. DOOLITTLE, manager Bingham-New Haven M. Co. at Bingham, Utah, has been in New York City.

A. F. ROGERS has been appointed assistant professor of mineralogy and petrography at Stanford University, Cal.

E. B. WILSON has been appointed dean of the faculty of applied science at Columbia University, New York City.

P. L. FERN of New York City has been examining mines for the United States M. Co. of Idaho at Bingham, Utah.

W. J. HOLDEN AND H. W. HOLDEN of Cleveland, Ohio, are at the Dutchman mine, near American Fork, Utah.

R. B. WATSON, consulting engineer of the Shannon C. Co. at Clifton, Ariz., has gone to Mexico on mining business.

M. PAGE has been made superintendent Republic mine, at Parrot's Ferry, 7 miles from Sonora, Tuolumne county, Cal.

M. J. HENEY, who has finished building the White Pass & Yukon Railroad in Alaska, has returned to San Francisco, Cal.

J. M. MCCLAVE, Denver, Colo., has charge of the construction work of the new zinc plant being built at Salt Lake City, Utah.

P. MIXSELL of Idaho Springs, Colo., has returned there from examining mines at Tonopah, Nev., and from a trip to San Francisco.

D. C. TOBIN, superintendent, has returned to the Continental mine, at Vulcan, Colo., from a trip to Denver, Leadville and Cripple Creek.

J. C. DUFRESNE has severed his connection with the Amalgamated G. M. Co. at Quartzsite, Ariz., and is examining mines near Mexico City, Mex.

A. H. ROGERS has resigned as manager Velardena M. & S. Co. of Durango, Mexico, to take up work as consulting engineer in New York City.

R. J. GRANT, who has resigned the management of the Cosmopolitan Proprietary, Niagara, Western Australia, has returned to the United States.

FRANK PARRISH AND ROBT. ANDERSON, the latter a former superintendent of the Le Roi mines at Rossland, B. C., have been examining mines near Park City, Utah.

A. T. CHARLTAN, a cyanide man of the Black Hills, representing Evans & Fennox of Colorado Springs has been examining the Continental gold mine at Vulcan, Colo.

W. H. BUELE, who was superintendent concentrator at the North American Copper Co.'s works at Encampment, Wyo., is now superintendent Cripple Creek Homestake M. & R. Co.'s cyanide mill at Cripple Creek, Colo.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

The copper production during 1904 amounted to 812,537,267 pounds, valued at \$105,629,845. The production for 1903 was 698,044,517 pounds. The most noteworthy increase occurred in Arizona, where both the Bisbee and Globe districts added largely to the product. The imports in ore and matte amounted to 38,947,772 pounds; the imports in bars, ingots and old bars to 142,344,433 pounds. The exports of copper amounted to 564,544,880 pounds, an increase over the exportation of 1903, which was only 326,322,627 pounds. The amount of copper consumed in the United States during 1904 was 485,284,592 pounds, a decline from the figure for 1903, which was 566,429,885 pounds. The production of merchant lead from the mines of the United States amounted to 307,000 short tons in 1904, valued at \$26,402,000. The yield in pig lead from ores smelted by works that treat argentiferous material is estimated, after undergoing the smelting, desilverizing and smelting operations, at 95% of the contents of the ores. The result is a tonnage of 218,000 for 1904, as contrasted with 199,000 short tons for 1903. To these figures are added 89,169 tons of soft lead for 1904 and \$3,444 tons of soft lead for 1903, making an approximate total of 307,000 short tons for the lead production of the United States in 1904, as compared with 282,000 short tons for 1903. Returns from all the producers of spelter in the United States show that the production for 1904 amounted to 186,702 short tons, valued at \$18,670,200. The production of 1903 was 159,219 short tons. This extraordinary increase in output was due chiefly to the growth of the industry in Kansas, where a number of new plants built in 1903 were in full operation.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The Bisbee Queen mine, in the Warren district, has been sold to E. E. Dennis of Michigan. Bisbee, June 12.

#### Cocconino County.

The asbestos deposits in the Grand Canyon of the Colorado river, Arizona, belong to the Hance Asbestos M. Co. of New York City, and are on the north side of the Colorado river, 70 miles west of north of Flagstaff, the county seat. The deposits are near the bottom of the Grand Canyon, 4900 feet below the rim, with a portion of the property rising to 1500 feet above the river. The nearest point on the railroad is Grand Canyon at the terminus of the Grand Canyon railroad, which connects at Williams, a distance of 63 miles, with the main line of the Santa Fe railroad. There is a good wagon road from Grand Canyon station to the head of Grand View and Red Canyon trails, which lead from the rim to the bottom of the canyon and are 14 and 19 miles respectively from Grand Canyon station. Both these trails are in good condition, and pack trains could carry from 80 to 100 pounds per burro or from 175 to 210 pounds per mule. Grand View, a United States post office, is on the rim between the two trails. The only present means of crossing the river to the asbestos deposits, which are on the north side, is by rowboat.

#### Gila County.

(Special Correspondence).—The Lost Gulch group, near Globe, belonging to E. F. Kellner, has made a trial run of fifty tons of ore with good results. The Lost Gulch group consists of six claims and is equipped with a 10-stamp mill with crusher, two copper tables, separator, two Frue vanners, 80 H. P. hoiler and 150 H. P. engine; also a 15 H. P. hoist for raising ore from the tunnel track to the upper floor of the mill. Globe, June 12.

Manager E. M. White of the Warrior Copper Co. states that the water has been struck in the well which the company is sinking in the gulch above the works, near Globe, at a depth of 32 feet. Sinking will be continued as long as practicable. As soon as a water supply is assured, mine development work will be begun in earnest.—F. A. Weast, superintendent of Tri-Bullion M. Co., has opened new horizons in the Starlight mine. The main drift is in 1657 feet and an upraise is being made 700 feet to the surface, also a winze is being sunk in good copper ore and the vein crosscut at 1400 feet in the drift.—N. L. Amster, of the Arizona Commercial Copper Co., has been at Globe conferring with Superintendent W. S. Sultan in regard to the development and future operation of the company's mines. Work is being done on the Copper Hill and Black Hawk mines. At the Copper Hill mine the new steam hoist and compressor are working steadily. A track has been laid from the Copper Hill mine to a junction with the United Globe tramway leading to the Buffalo ore house. At the Black Hawk, the shaft has reached a depth of 115 feet and both drifts and crosscuts are being run all in ore. The company has under consideration plans for marketing their ore, or, if found more profitable, erecting reduction works of their own.

#### Graham County.

(Special Correspondence).—The output of the Arizona Copper Co. for May was 1412 tons of copper. The company has about 4000 acres, including mines at Morenci, Metcalf, Longfellow, Garfield and Coronado, the principal mines being the Humboldt, at Morenci, and the Longfellow, which was the first copper mine opened in Arizona. The ore occurs as disseminated sulphides. The mines are worked open-cast and the product is of two grades, one-tenth being smelting ore and nine-tenths concentrating ore. Ore is taken from the different mines over gravity trams to storage bins on the Coronado railroad, which the company operates. Morenci, June 13.

(Special Correspondence).—The output of the Shannon Copper Co. for May was 691 tons of copper. Superintendent Schofield of the Coronado Copper M. Co.

has commenced sinking a double compartment shaft on what is known as the big Coronado vein. Metcalf, June 13.

#### Mohave County.

O. F. Kuencer, superintendent of the German American mines at Acme, reports that the new mill will be dropping stamps about July 15.—The Benedict M. Co. of Washington, D. C., has taken an option on the mines of J. P. Ryan, W. Jennings and others in the Cedar district, and on Aug. 1 are to begin development on a large scale. The mines are near the San Francisco.—O. Stein, who has been unwatering the Tennessee mine at Chloride, reports having opened up a fine body of lead ore on one of the outside claims of the Elkhart group and is working men on it.—It is reported that the crosscut at the 600 level of the Gold Road mine has reached the hanging wall and 40 feet of ore has been cut. The ore is of a high milling grade and more easily worked than the ore above that level.

#### Pinal County.

(Special Correspondence).—The Bunker Hill mining district is 12 miles east of Mammoth. The district has long been held back for the want of railroad facilities. This is about to be overcome and much activity is noticeable in consequence. The Michigan-Arizona M. Co. are operating six claims. Large deposits of copper carbonate and glance ores crop out on the surface of every claim. On close examination there can be found considerable native copper mingled with the ore. Every assessment hole that has been dug shows good ore. A 50-foot prospecting shaft was sunk, with a 20-foot crosscut at the bottom, all in good ore. They are now driving two tunnels from opposite sides of the mountain, and when these are completed they will have nearly 400 feet of tunneling in the ledge, with nearly 200 feet of stoping ground. Two shifts are driving the work and, as soon as sufficient ore is blocked out, they will build a smelter at the mine. The home office is at Safford, Ariz., and stock office at Muskegon, Mich. One mile north from the above property are eight claims, owned by C. Dixon and P. Figueroa. On the Black Metal there is a 25-foot ledge, which averages about 10% copper, with gold and silver. The Silver Bell has an 18-foot ledge on the surface and carries 12% copper. The Monarch has a 20-foot shaft which is in carbonate ore, averaging about 15% copper. To the north, 3 miles, is the Giant group, owned by Clark & Scanlin. It consists of five claims, with a mineral zone 300 feet wide, on which have been dug eleven shafts varying from 10 to 75 feet in depth, and all show good copper ore running from 10% to 60% in copper. In a southerly direction are two claims owned by the above, on which was a 35-foot shaft, the bottom of which was connected with a 50-foot tunnel. This work had uncovered an 8-foot ledge carrying 25% lead and 60 ounces in silver. To the northeast the Concordia group, consisting of three claims, is near the head of Copper creek, and owned by Clark & Morgan. From a 3-foot ledge two trial shipments were made, running 28% copper, 46 ounces silver and \$5 gold. Near this is the Sibley M. Co., operating a group of twenty-five claims. They are taking out some high-grade copper ore carrying silver. A wagon road is now under construction. They contemplate installing a smelter the coming fall. The two claims held by Alex. Rosi, lying between the Clark and Sibley groups, made a sample shipment from a 12-foot ledge which returned 40% copper and 140 ounces silver. The Hawkins group, close to the Giant group, is rich but small. A shipment returned a large percentage of lead and 1500 ounces in silver. Adjoining the Giant group is a claim owned by E. W. Childs of Mammoth, which is rich in lead, with a small amount of silver. From this a shipment was made showing 60% lead and 20 ounces in silver. He has three claims which adjoin the Giant group which carry copper. The two claims owned by J. Keigle adjoining the Giant group have the same formation and copper values as the Giant group. J. Mercer holds the Old Smelter mine, which was worked years ago by the Mexicans. In the face of a 60-foot tunnel is a 30-inch ledge high in silver. Much of this ore was smelted in the early days in an old adobe smelter on the San Pedro river. R. M. McKinney & Son hold the Longstreet copper mines, located on Copper creek. A tunnel 25 feet and a shaft 15 feet are in ore running from 5% to 40% copper.

There are some important negotiations pending on some of the above properties, and the construction of the railroad, which will be completed this year, leads to the conclusion that there will soon be much activity in the district, although there are only two companies in active operation at present, the Michigan-Arizona M. Co. and the Sibley M. Co.

Safford, June 12.

E. R. Stafford, superintendent of the Arizona-Pacific Copper Co., 7 miles south of Kelvin, states that the shaft is down 320 feet and a crosscut at the 300-foot level has cut an ore body that is 22½ feet wide. The shaft will be sunk several hundred feet deeper. Two 60 H. P. boilers, a 35 H. P. steam hoist, a 50 H. P. compressor and an electric lighting plant capable of furnishing 200 lights have been put in at Woolley.

#### Yavapai County.

Work has been resumed at the Peck mine, near Prescott.—F. A. Bowman is working the Rainbow group in the Bradshaw mountains, south of Prescott.—The shaft of the Bauman Copper Co. in the Agua Fria district, 2½ miles from Val Verde, is being sunk 4 feet per day. The company has 500 acres, showing fissure veins carrying sulphide ores giving values in copper, gold and silver.—New machinery has been put on the Little Jessie group, near McCahe, by J. S. Jones.—H. A. Kendall, developing the properties of the Yavapai Copper Co., near Prescott, states that W. F. P. Fogg intends to explore the properties with diamond drills and also drive a tunnel through the Black Hills, to allow the cars of an electric railroad to pass through—this road to traverse Lonesome valley and connect the Verde valley and Prescott.

The Congress mill, at Congress, has forty of its eighty stamps dropping on ore from the mine.

#### Yuma County.

(Special Correspondence).—The Amalgamated Gold

Mines Co. have closed down their mines at Quartzsite, pending the result of a lawsuit.

Quartzsite, June 12.

A. J. Morse is putting up a cyanide plant at the Bonanza mine, near Harqua Hala.

The Socorro mine, at Harrisburg, has twenty-five men opening up new ground and stoping ore. The remodeled 20-stamp mill has been running since May 1.

### CALIFORNIA.

#### Amador County.

C. L. Maze has been working on the chlorination dump of the Kennedy mine near Jackson. These tailings contain from \$5 to \$10 per ton in gold.—The Madrone mine, near Jackson, in the Pioneer district, is being worked by C. F. Leslie and J. Fredericks.

#### Calaveras County.

A rich strike is reported as the Royal mine at Hodson. On the 100-foot level a cross vein which has been traced to the surface was located. It is said to be 50 feet wide on the 500-foot level. This lies above the flat vein and is between the diabase and slates. An English syndicate, represented by J. C. Kemp Van Ee, controls it, though J. H. Brotherton recently secured a judgment for one quarter of the mine. J. T. Hodson owns a half interest.—The Yellow Boy M. Co. will start work on the Red Gold and Gum Boots mines near Murphys. Campbell and C. V. Zinn of Murphys are interested.—Good ore has been found at the Hercules Horseshoe mines at Indian creek, near Murphys. L. L. Washburn has charge. The mill has been running.

#### El Dorado County.

The Mameluke Hill hydraulic mine, which has closed down on account of a large landslide in the mine, will not resume operations until next fall. Superintendent Sargent states that the Loon Lake Water & Power Co. could not guarantee to furnish the mine with the required amount of water to continue operations during the summer months.

#### Mono County.

Reed Smoot of Salt Lake City; L. L. Nunn, manager of the Power Co. at Telluride, Colorado, and L. Holbrook of Utah, have purchased the Syndicate mines near Bodie. They will establish a large power plant on the Walker river, and will operate mines on a large scale. The Syndicate mine is on the north slope of the Bodie ridge, 1 mile from Bodie. The Syndicate tunnel cut through 200 feet of volcanic breccia before reaching the andesite in which the veins are found.

#### Nevada County.

Work has been started on the new 10-stamp mill at the Chicago mine, near Grass Valley, which is expected to be finished by August 1st.

G. Baldwin has bought the Manhattan mine at Gold Flat, near Nevada City, to Moss & Co. of San Francisco. The holders propose to commence active work on the mine and will sink a new shaft. The old shaft is down 270 feet.

A new gallows-frame and a large ore bin are being put up at the New Orleans mine, near Grass Valley. Good progress is being made on the trench for the water pipe from the Sultana.

The Springhill Con. M. Co. has been formed to develop the Springhill mine near Grass Valley, and the management is negotiating with the owners of the Maryland mill for the use of its plant in milling their ores. G. B. McDonald of New York is president, J. A. Kirby of Utah vice-president and W. A. Byrne of Salt Lake City, Utah, secretary and treasurer, C. B. and J. M. Lakenan of Grass Valley directors.

#### Placer County.

F. Armstrong of Grass Valley, superintendent of the Golden West gravel mine at Canada Hill, east of Westville, is starting work and will run three shifts during the season.—H. Blagrove, superintendent of the Canada Hill Quartz M. Co., is running a double shift, six men, on their mine and mill.—The Tadpole mine, near Secret House, the Black Canyon mine and the Santa Fe mine are being opened up.

#### Shasta County.

The new 5-stamp mill of the Marina Marsicano M. Co. at the Sunny Hill mine, near Ono, has been started. L. F. Barlow reports satisfactory results. A new Pelton wheel is being put in to furnish power for the air compressor, which operates the drills in the mine. Work on the proposed cyanide plant below the mill will not be begun until all the other work has been completed.

The Bullychoop mine, west of Redding, is to be reopened and operated by a company of which W. R. Beall is the manager. J. S. Stevenson is assayer.

#### Sierra County.

C. C. Weisenherger of Nevada City is at the Two Counties mine, south of Alleghany, building a 5-stamp mill.—The upraise from the new tunnel of the Oriental mine, south of Alleghany, has been connected with the 400-foot incline shaft from the surface. The lower tunnel was started from Kanaka creek, 800 feet vertically below the shaft, and was run 4000 feet to the vein; 3500 feet of it is straight and without a stick of timber. It is 9 feet wide and 7 feet high. The upraise is over 700 feet long. H. L. Johnson is superintendent.

#### Siskiyou County.

J. E. McBride, one of the principal stockholders in the Headwaters mine at Humbug, and J. H. Tihitts of Redding have started work at the mine.—Superintendent Wardner, of the Mono mining claim at Punch creek, near Yreka, is prospecting and developing the Jenny Lind group of mines adjoining the Mono on Humbug. The Mono Co. intend constructing a cyanide plant.

#### Sutter County.

Assays of drillings in gold-bearing sands on W. T. Phipps' land near O'Banion Corners have proved so low that the sands cannot be profitably treated at present.

#### Tuolumne County.

F. McPherson and a company has started work on the Hazel, on the East belt, near Columbia. The old shaft, 200 feet deep, will be cleaned out and a new shaft will be started, 200 feet north of the old one.—It is reported that W. A. Nevills will start the pumps at the Moody mine, near Big Oak Flat, preparatory to resuming work.

## COLORADO.

The three forest reserves heretofore known as the Pike's Peak, South Platte and Plum Creek forest reserves have been consolidated into the Pike's Peak forest reserve, with the inclusion therein of additional areas and the elimination of a small tract, and two additional adjoining reserves have been established, the Leadville forest reserve and the Gunnison forest reserve. The Pike's Peak reserve embraces 1,581,667 acres, the chief expansion having been made on the north, to include a region around Mount Evans of 279,730 acres, with a view to remedying, in the interest of the city of Denver and the South Platte valley, the shortage of water in the South Platte river, which has long been an increasing trouble as the region develops. The Leadville forest reserve embraces 1,219,947 acres, and includes all of the Arkansas river watershed lying north of the south line of township 51 of the New Mexico principal meridian, and the watersheds of the Blue and Williams fork rivers, in the counties of Grand, Summit, Lake and Chaffee. It contains the highest and most important mountain area in the State. In length this general tract extends 100 miles, including the town of Buena Vista on the south and extending almost to Sulphur Springs on the north, with an average width of 25 miles. The valley of the Arkansas river, in which Buena Vista is located, and that of the Blue river have been excluded from the reserve. The establishment of the Leadville reserve is of importance to the mining industry, since the need for carefully controlled use of the remaining timber is of vital importance to such mining districts as Leadville, Breckenridge and Montezuma, which are within its limits. The Gunnison forest reserve includes 901,271 acres of the Gunnison river watershed in Gunnison, Delta and Montrose counties. The chief object of the reserve is to insure the success of the Uncompahgre valley irrigation project.

## Clear Creek County.

The Moscovite mine, on Democrat mountain, near Georgetown, has been bonded and leased to S. H. and R. D. Clift of Denver, who will start work on it.—The Domingo M. Co. will develop the Domingo claims in the Argentine district. The tunnel is in 270 feet. The company has made arrangements with the East Argentine Co. for the power with which to operate power drills. The incorporators of this company are H. J. Crist and H. Cochran of Georgetown, and Zimmerman Bros. of Marshallville, O.—F. A. Maxwell has sold to the Gold Fissure G. M. Co. the Annex, Gold Fissure, Gold Dirt No. 2 and Laura Doano lodes, in the Empire district.—The New Era mine at Freeland is running steadily, supplying ore for the 40-ton mill recently started. J. R. Elgan of Denver is superintendent.—The Nabob claims, on Columbia mountain, is being operated by C. W. Benkleman of Denver and G. Pease of Georgetown. The lower level has been driven 1100 feet and the upper level 1300 feet.—High water recently washed out the dump at the Seven-Thirty mine, near Silver Plume, filling with debris the blacksmith shop, the oil and tool rooms and the boiler room. It also washed away part of the flume and covered the floor of the orehouse with water.

R. C. Vidler has ordered for the Vidler tunnel, near Georgetown, an 80 H. P. boiler; a filter for the mine water; an air receiver 10x4: 1000 feet of 10-inch air-pipe; small horizontal engine to be used in running an exhaustor; 2000 feet of 3-inch wrought iron pipe for the compressor, capable of furnishing 500 feet of air; and model No. 5 water-Leyner drills. The tunnel will be equipped with 16-pound rails. The Vidler tunnel is in 700 feet and during the work seven veins have been cut. Superintendent L. W. Vidler expects to increase the force.

The Commodore M. Co. has started work on its tunnel, into Red Elephant mountain, near Lawson.

## Gilpin County.

The Colorado M. Co. has been formed by Centerville, Iowa, parties with C. A. Farrington president, J. R. Needham vice-president, and F. Augustus secretary, to work claims in Gambell gulch. It is reported that O. J. Duffield of Rollinsville will be manager.—The machinery on the Hope and Parker claim in Phoenix district has been moved to the Gold King mine in Moon gulch, which has a shaft down 100 feet and is owned by G. Carle of Denver.—The Silver Lode in Moon gulch has been leased and bonded by Potter & Lightbourn of Central City to W. G. Smith and W. H. Knowles, and arrangements are being made for putting in machinery for the unwatering of the main shaft, which is reported to be down 150 feet.—J. A. Gilmour of Central City has ordered a new shaft building, to be 20x40 feet, and a 25 H. P. hoist and boiler for the Daisy extension on Perigo hill. The shaft is down 125 feet and Gilmour expects to sink it at least 100 feet as soon as the surface water is out. Shipments will be made to the Daisy mill in Gambell gulch, which is equipped with fifteen slow-drop stamps, tablos, bumpers, etc.—At the Castleman mine, near the head of Virginia canyon, W. M. Kirk of Russell gulch is working chiefly in the 300-foot levels. The shaft is down nearly 400 feet, one lift of 100 feet being sunk with three eight-hour shifts in twenty-three days. They expect to resume sinking to the 500-foot point. Drifts are to be extended at a depth of 400 feet as soon as the shaft is freed from water. The Lucania tunnel being driven in from Clear Creek will cut under this property at a depth of less than 1000 feet and about 800 feet west of the main shaft and it is believed that this will solve the drainage problem and will in the future, when the Castleman workings are down to the same depth, furnish them an exit for their shipments, furnishing cheaper transportation and also cheaper mining operations through the drainage of surplus water.—H. B. Gilbert & Sons are working the Star of Gilpin mine in the Russell district under a three-years' lease and bond. They are drifting west at a depth of 150 feet and are also uprising to the 100-foot workings for air connections, having been troubled with bad air.—It is reported that heavier machinery is to be put on the Golden Cloud, at the head of Virginia canyon in the Russell district by Potter & Hawley of Central City. The main shaft is down 500 feet, and, on account of surface water, operations have been handicapped because of

banding the additional water. Concentrating ores are being taken out at the 200-foot workings and are being shipped to Idaho Springs.—It is reported that the Franklin mill, east of the Black Hawk depot, is to be started up and that a cyanide process will be put in to handle ores from the Pine Creek and surrounding districts.

G. W. Goodyear of Central City has purchased from W. F. Thick of al. one-third interest in the After Supper mine, in Enterprise district, near Black Hawk, for \$7000. The After Supper lode is considered to be an extension of the Fisk and Sleepy Hollow leads and is being operated by the Banzai M. Co.—The Gower Mines Syndicate, Ltd., has purchased the Bant lode, in Gregory district, southeast of Black Hawk, for \$1300.—The Modoc mine, on Quartz hill, near Nevada, is being operated under lease and bond by the United Exploration Co., with F. Straub of Denver as manager. Stopping operations are being carried on in the 200-foot east and west levels, where the ore bodies have been opened up for a width of 25 feet. Ore is being shipped to the Hidden Treasure mill. The company will soon put in heavier machinery and larger shaft buildings. The shaft is down 230 feet, but no sinking operations will be carried on for some time, as there is enough ore in sight to last for a number of months.—The Elizabeth G. M. Co., operating the James Henry mine, have men on the 200-foot level sinking a winze in ore, which will be prospected before extending the 300-foot level under it.

## Gunnison County.

Work has been started on the Bellview Mt. mine, near Crested Butte. A. J. Vagg and C. W. Espey of Chicago, Ill., have been at the mine.

## Hinsdale County.

The Lone Star mine, near Lake City, has struck high-grade ore.—The Moro & Ajax Co. are rebuilding and enlarging their mills at Capitol City, and will soon be able to make a large output from their Moro and Ajax mines. The mine and mill are connected by tramway. A pipe line and power plant are to be constructed during the present season, which will lessen the cost of production in both mine and mill. This property is 11 miles from Lake City on Henson creek, near Capitol. G. H. Martin of Chicago is general manager.—The Hidden Treasure mine, under lease to L. Kafka of Lake City, is working a full force on both mine and mill. The mine is worked through a shaft and seven levels are opened. The mine and mill are connected by tramway. P. C. McCarthy has charge.—The Waldron property, in the Mineral Point district, near the headwaters of the Animas river, is owned by the Adelia M. Co. The shaft is 250 feet deep.

J. D. Irving, in describing the ore deposits near Lake City, says that the deposits are along the course of Lake Fork to 5 miles south of Hinsdale and along Henson creek westward through Henson and Capitol City for 10 miles, chiefly in the stream bluffs. Henson creek cuts through rhyolite flow breccias characterized by undulatory banding and inclusions of rhyolite and other rocks. These are intruded by andesite porphyries appearing as irregular dikes. Irregular beds of volcanic tuffs and agglomerate become more numerous to the south. The rock series is traversed by numerous faults, at some places heavily mineralized. The ores are found in silver-bearing fissure veins and in gold-bearing fissure veins. The ore minerals of the silver-bearing veins are galena, tetrahedrite, chalcopryite, sphalerite and pyrite.

## Lake County.

At the Forest City, Little Ellen hill, near Leadville, the drift from No. 2 shaft is being driven ahead to make connections with No. 1 shaft, which will give the mine good air. No. 1 shaft is close to the end lines of the Winnie, and it is expected that before the drift reaches this distance the Winnie ore channel will be cut. At the Izard's new shaft satisfactory progress is being made.—Prospecting is still being done at the Triumph, at Leadville.—The Sedalia shaft, near Leadville, has been unwatered and the ore bodies in the lower levels are being worked.

## San Juan County.

J. Pilling has resumed operations on his claims on South Mineral creek, near Silverton.—The Gold King Con. M. Co. of Silverton is shipping seventy-five tons of concentrates daily to the smelters.

O. S. Olson & Co. have resumed work on the Early Bird mine on Houghton mountain, near Animas Forks.

## San Miguel County.

A good strike has been made in the Japan-Flora mines in Savage basin, owned by the Japan-Flora M. Co. While drifting north on the Japan vein in the lower workings in the direction of the Flora, a cross lead was encountered which carries from 10 inches to 3 feet of silver and lead ore, with some gold. A new mill will be built at Pandora, 2 miles above Telluride, at the head of the valley, where the Smuggler-Union mills are located, and will be connected with the mines by an aerial wire rope tramway 2 miles in length.

## Summit County.

The Victoria of the Masontown M. & M. Co. on Royal mountain, near Frisco, has been opened by an adit tunnel for 600 feet. The ore is stamped, amalgamated and cyanided in a 50-ton mill.—On the same mountain the Copper Queen, owned by Memphis people, is being worked with twenty men.—On Wichita mountain, opposite the Copper Queen, the Excelsior mine is opened by adits. The company has a concentrator near the mine capable of handling 80 tons daily. The ore is a lead-copper sulphide.—The Admiral Co., operating in Ten-Mile range, 3 miles above Frisco, is preparing to pipe most of the water in Ten-Mile creek to generate electric power for all the mines in that region.

The Abundance M. & M. Co. has put in a new pump, boiler and water line to supply water for the boiler at the hoisting plant.—The Sarsfield, the Washington and Modoc mines at Montezuma have been merged into one group by Chicago parties under bond and lease. The work at the mine is in charge of J. Sutherland.—The Clarion mine at Montezuma is being started up by C. H. Campbell and associates.—C. W. Smith has six men at work in the Silver Wing, near Montezuma, taking out some good zinc ore.—T. Connors will re-

open the Wild Irishman at Montezuma with machine drills.

The Morning Star mine, on Mount Baldy, near Breckenridge, and owned by W. P. Conlon, has been started.—The leasers of the Rose of Breckenridge have found zinc ore in the upraise above the drift on the main tunnel level.—At the Summit Banner Placer Co.'s workings, 2 miles north of Breckenridge, men are enlarging and repairing the dam, building flumes, clearing right-of-way for a 3800-foot pipe line and clearing out old ditches.

## Teller County.

Lessee Smith has started work on the Sentinel claim on Raven hill, Cripple Creek, which has been shut down because of surface water.

The Havana-Clyde G. M. Co. has acquired by purchase the Raymond, Dakota and Fannie A. claims, near Clyde. E. J. Leach has been appointed resident agent of the company at Cripple Creek.—McDonnell & Long, who have the Elkhorn on Tenderfoot hill, Cripple Creek, under bond and lease, are sinking. The shaft is now 450 feet deep.

The Exposition Mines & Leasing Co. is moving the hoist from the Caledonia mine to the Los Angeles mine, near Cripple Creek, preparatory to taking out ore from the 900-foot level. This will be treated in the cyanide plant now almost completed.—Good speed is being made by the Omaha Leasing Co. in its shaft sinking on the Norfolk claim of the Empire State G. M. & M. Co. of Ironclad hill, Cripple Creek. Sinking was started near the surface. A recent measurement shows a depth of 135 feet. As soon as hard rock is reached a lateral will be started, but the shaft will be continued to the 300-foot point. O. M. Deemer of Omaha, Neb., is manager of the leasing company.

Sinking has been resumed in a winze on the Morning Star claim of the Acacia Co. on the northeast slope of Bull hill, Cripple Creek.—F. Bowen and associates are prospecting at the 400-foot level of the Kitty Lane property of the Gould Co., Cripple Creek.—The Black Diamond and the Friday on Tenderfoot hill, Cripple Creek, have started shipping.—The Golden Cycle M. Co. will sink the 1000-foot to the 1100 level. Five shoots in the Golden Cycle have been opened for stopping on all levels between the surface and 800-foot level. Crosscuts have been driven on the ninth and tenth levels showing the same bodies.

C. L. Cleaver is putting in a washer to treat the dump of the Henry Adney mine on Beacon hill, Cripple Creek.—It is reported that sinking is to be resumed from the 265-foot level of South Burns block, which is being worked by the Exposition M. & L. Co. They are hauling the machinery of the Wrockloff shaft of the Acacia Co. to the South Burns.—The El Paso Co. will start up the Beacon Hill-Ajax mine, near Cripple Creek.—J. S. Murphy, operating on the Monte Cristo, on Beacon hill, has the shaft down 350 feet and has a good vein.—The City of Cripple Creek G. M. Co., which is operating under the city, continues sinking at the Meise shaft, on the corner of Fourth and Myers avenue. As soon as the shaft has reached a depth of 500 feet, lateral work will be started. The company is also sinking on the Maid of Orleans claim, on Beacon hill. Work at a depth of 400 feet has been started—sinking another lift of 100 feet—when crosscutting will be started to reach the El Paso, Old Gold or C. K. & N. dikes.—It is reported that work is to be resumed on the Golden Wedge property, on Raven hill. The shaft is down 350 feet.—F. G. Conover is working east of Goldfield on Big Bull mountain.—Webster and associates, operating under lease the International claim on Gold hill, Cripple Creek, are working on a 3-foot vein at a depth of 350 feet, sinking a winze to the 400-foot point.—The Fort Pitt Co., operating the Sunshine claim, on Galena hill, will sink the main shaft an additional 300 feet, which will give a total depth of 800 feet. The mine is the most northeasterly producing mine in Cripple Creek.—Operators in the Maid of Orleans claim, on Beacon hill, have commenced sinking another lift of 100 feet on the claim, which will give a total depth of 500 feet.—The cyanide mill which is being built by the Little Giant M. & M. Co. in Tony gulch, 3 miles from Cripple Creek, is nearly completed.

A heavy flow of water has been struck in the C. K. & N. mine, Cripple Creek district, which has caused a suspension of operations in the bottom of the shaft, which had reached a depth of 860 feet when the round of holes fired cut the water seam. It is stated that the water rose in the shaft in four hours to the 740-foot point. As there is no adit through which this water can be drained without pumping, the management is considering the advisability of putting in heavy pumps, particularly as this unexpected flow of water is thought to indicate the proximity of an ore body of good size. This latest flow of water indicates the necessity of the proposed deeper drainage tunnel.—At the El Paso shaft sinking continues. The pumps are handling a large amount of water from the C. K. & N. workings.—A leaser on the Independence has struck a lead in which there is a rich pay streak. The management is endeavoring to oust the leaser, who has sued for an injunction restraining the company from depriving him of his lease.

## IDAHO.

## Boise County.

Blaine & Co.'s dredger, near Placerville, will probably be ready for work by August 1.—It is reported that the owners of the Mineral Hill mine, near Quartzburg, will put in a hoist and start production.—The old Iowa 10-stamp mill is being hauled to the Belshazzar mine, near Quartzburg, by D. E. Coughanour.—The Gold Hill mine, near Quartzburg, is being unwatered preparatory to running a tunnel from its shaft to open up the Iowa.

G. Z. Edwards, superintendent of the Lincoln mines and mill in the Pearl district, reports good progress on the new cyanide plant. The new shaft is down 340 feet, with a crosscut being extended to the ledge.

## Idaho County.

The management of the Gold Reef M. & Dev. Co., whose properties are on Thunder mountain, near Roosevelt, has closed a contract for a plant with which to reduce thirty tons of ore daily. C. E. Croh is directing

operations at the property. The lumber for the mill is being turned out at the company's sawmill in Thunder Mountain.

J. B. Whitlock, superintendent of the H.-Y. mine at Roosevelt, in the Thunder Mountain district, states that there is much work going on in the district. The roads are almost impassable for even a pack train beyond the transfer. Packers are asking from 8 to 10 cents a pound for packing freight from the transfer to Roosevelt. The H.-Y.-Climax shaft, which is down 265 feet, is to be used as the working shaft.

#### Owyhee County.

The Cumberland mill, near Silver City, is running one battery of stamps on ore from their mine. There are eleven men at work, but little can be done until the Sinker tunnel draws the water from the shafts and drifts. F. Jenkins is superintendent.

The Banner mines, west of Coffee gulch on the west side of Florida mountain, near Silver City, are to be developed by the newly organized Banner M. Co., in which L. S. Honstead, P. Steele and F. S. Herr, all of Silver City, are interested. The lead carbonate deposits on South mountain, near Silver City, are being worked by F. M. Clemmens of the Standard M. Co. of Denver, Colo.—W. Lacherity has purchased from Connors & Evans the John-Bill mining claim on War Eagle, near Silver City.—A. F. Stevens, manager of the Rich Gulch Co.'s mine on the south side of Jacob's gulch, Florida mountain, near Silver City, has men at work advancing the tunnel on the vein, which is reported to be making a good showing.

#### Shoshone County.

The Beartop M. Co.'s mill near Murray is completed. The capacity is 150 tons a day, but additional machinery is to be put in as soon as better transportation for the output is secured. It is driven by water power. The flume is 8000 feet long, and at the mill the water has a drop of 450 feet. Work in the mine has been started.

The Idaho-Nevada M. Co. have elected as president H. J. Rossi; secretary and business manager, W. J. Bracking; vice-president and superintendent of mines, O. R. Young. The company now has miners at work on its Wallace property.—The litigation between the Nine Mile M. Co. and Mary Kate Wylie of Murray has been settled out of court. Each party owned a half interest in the Topeka lode, 4 miles from Wallace, which the Nine Mile Co. considered the best in its group of claims, and as Mrs. Wylie would neither consent to sell nor work her interest in the property in conjunction with the company, the latter brought suit for a division of the property. It is the suit which has been compromised, Mrs. Wylie deeding her half interest to the company for a cash payment and 50,000 shares of the company's stock.—The Pittsburg Lead M. Co., which is operating the Black Cloud and California and the Panhandle groups on Nine Mile creek, has completed the purchase of the latter property, which it has had under bond. A. D. Marshall, formerly superintendent of the Standard mine at Mace, is in charge of the operations of the Pittsburg Co. The company has 120 men on its payroll and is planning to equip its mines and mill with electric power so that it may be able to work continuously without being hampered in the dry season by lack of water. The mill is making regular shipments of concentrates to the American Smelting & Refining Co.'s smelter at Pueblo, Colo.—The Wake-Up-Jim G. M. Co. has elected G. M. Ward president; J. A. Ward, vice-president; C. S. Cryslar, secretary-treasurer and general manager. The Wake-Up-Jim is at the head of Trail creek, near Wallace. Work will begin upon a 100-foot tunnel with eight-hour shifts. The ore is largely free milling and the sulphurets yield to treatment by cyanide. It is reported that a 10-stamp mill with cyanide plant will be placed upon the property.

The Stanley M. Co., which owns claims south of the Morning mill, near Mullan, is preparing to resume development work on the property.

Judge Beatty has refused the injunction asked for by a number of farmers on the Coeur d'Alene river against mining companies of Coeur d'Alene that tailings from mills were deposited on lands of plaintiffs at high tide, poisoning the grass and hay. The judge not only denies the injunction, but criticises the plaintiffs. Judge Beatty enters into the question of contradictory affidavits filed regarding the presence of poisonous substances in the waters of the river as asserted by chemists on either side, and concludes that the court would be unable to justify itself from these affidavits in issuing a restraining order. The court further says that the granting of such an injunction would shut down the mines and depopulate the district.

At the annual meeting of the Sister M. & M. Co., at Wallace, S. Markwell was elected president and treasurer, C. V. Genoway vice-president, C. W. Gossert secretary and J. E. Markwell manager. The management is planning to sink a 3-compartment shaft, the work of which has already been started.—There are 3 feet of ore disclosed in the recent strike in the Hercules mine, at Burke, in a drift run from No. 2 tunnel.

#### Washington County.

The Little El Frieda M. Co. is working on War Eagle mountain, near Warren. W. C. Colwell, the general manager, has started work at the mines and has ordered 1000 feet of track rails, ore car, hand-power drill and other supplies. He has also ordered a complete assaying outfit.

From Landore, in the Seven Devils district, it is reported that the Ladd Metals Co. is preparing to start mines and smelter. The smelter will be overhauled and reverberatory furnaces substituted. A large amount of fuel is being accumulated and men are being placed at work in the company's properties. The bins contain 2000 tons of ore ready for the smelter.

#### MISSOURI.

##### Jasper County.

The Joplin News-Herald says that the North Main Street M. Co.'s mill is shut down temporarily.—D. M. Sayres is sinking a shaft to open up a prospect on the O'Keefe land.—O'Connell & Co. are operating the Old Rollin mill, at Midway, working on tailings.—Thompson & Co. of Joplin have started up the Ringo mill on

the O'Keefe land.—The Last Chance M. Co. is preparing to resume operations on the O'Keefe land.—The Denver M. Co. has begun drilling on their 200-acre lease of Oakland.—The Jayhawk M. Co., operating on a lease on the Amazon land, has its shaft down 140 feet.—An 8-inch pump has been installed at the old Orchard mine, on the Cox land, by F. Malang and others.—The Lillie M. Co., operating on a 40-acre lease on the Amazon land, has started up its new mill.

#### MONTANA.

##### Beaverhead County.

J. C. S. Wells of New York has resumed work at the Polaris mine at Polaris, belonging to H. H. Armstead, Jr., et al., and is shipping silver-gold ore.

##### Broadwater County.

Work is being pushed on the Mason properties, the Park and New Era, near Hassell, under the direction of Mr. Atwater, who has been made managing engineer. The shafts and upper levels have been unwatered and connections are being made with the lower tunnel this week. During the past month tests have been made of the oxides, showing that a saving of over \$8 per ton can be made, and a cyanide plant is contemplated, in addition to the 100-ton concentrator. The concentrator will be started as soon as the lower and upper workings are connected so the ore can be taken to the mill at low cost.—R. A. Bell, owner of the East Pacific mine at Winston, has started work on a concentrator on the property, which will be ready to run by the 5th of July. With this mill he will work 20,000 tons of ore on the dumps with an equal amount of second-class ore left in the stopes. It is reported that D. P. Little will have charge of building a cyanide plant at this mine.

##### Cascade County.

Roehl Bros. of Neihart have started their new concentrator on ore from the London mine, upon which they have a lease.

##### Deer Lodge County.

The Gold Coin 30-stamp mill, 3 miles from the Cable Lease property, near Anaconda, is in operation on ore from its own mines, and it is understood that the operators of the mine are working on a large body of low-grade gold rock.—The Southern Cross property, 1 mile from the Cable, is being worked with forty men. The roads in that section have been bad for quite a while, and no ore has been shipped on this account, but there are 500 tons on the dump ready for shipment. The new cyanide mill is about ready to receive ore. The high-grade product of this property is to be treated elsewhere, but the lower grade will be run through the mill and cyanide plant.—A strike of high-grade gold ore is said to have been made on the Montana claim in that district, owned by J. Ducie of Anaconda and M. Gaffney.—A United States Geological Survey camp has been established near Anaconda to make surveys of the mining districts west of Anaconda. The work will be under the direction of H. L. Baldwin, Jr., of Washington, D. C.

##### Fergus County.

In sinking with a diamond drill to find ore on the Bullard claims at Kendall the St. Paul syndicate that acquired the property over two months ago has struck oil. When a depth of 400 feet had been attained oil gushed out before the hole could be plugged. The flow is said to have reached about twenty gallons a minute.

##### Jefferson County.

O. B. Whitford of Butte, who owns the State mine in the Bigfoot district, 12 miles southwest of Boulder, in the Whitetail range between Boulder and Whitehall, reports an excellent body of high-grade ore in the face of the 500-foot tunnel, which he and Mr. Lyon have been driving into the mountain.

##### Madison County.

A. Bradberry, of the Conray Placer M. Co., operating on the Ruby river in the Ruby mining district, reports that there are two dredgers at work, which are handling nearly 2000 cubic yards of gravel per day, and another machine of larger capacity is being put in.—The Revenue mill, near Norris, has resumed work after a short shutdown.

##### Silver Bow County.

(Special Correspondence).—The Amalgamated sub-companies of Montana have made their annual statements to the county assessor at Butte for the purpose of taxation on net earnings. The total output of ore for the year ending June 1, 1905, was 3,293,584 tons, and the gross yield \$33,749,397.16. Total cost of mining, \$10,949,811.85; paid out on freight, \$1,484,807.27; cost of reduction, \$8,626,381.82; cost of marketing, \$3,647,183.53; net earnings, \$8,692,243.52 against \$6,240,025.54 for the year ending June 1, 1904, an increase of \$2,452,217.98. The following figures showing tonnage of ore, gross and net proceeds will be interesting for comparison:

	Tons.	Gross.	Net.
Boston & Montana.....	1,138,307	\$14,634,923.46	\$5,855,620.07
Anaconda.....	1,473,644	13,787,315.07	2,259,693.73
Parrot.....	167,963	1,448,551.37	338,106.69
Trenton.....	150,295	817,421.35	70,110.23
Butte & Boston.....	250,433	1,932,837.12	178,712.81
Washoe.....	102,941	1,097,018.79	.....

Butte, June 12.

For the year ended June 1, 1905, the Amalgamated Copper Co. earned \$8,692,243.52—\$2,452,218.98 more than for the year ending June 1, 1904. The statement was filed with the assessor of Silver Bow county for taxation purposes as follows: Anaconda, \$1,259,875.91; Parrot, \$233,964.68; Trenton (Colorado), \$74,832.35; Butte & Boston, \$96,853.48; Boston & Montana, \$4,574,498.12. The total shipments of the Amalgamated smelters is placed at over 10,000 tons a day, 7000 of which is being sent to the Washoe smelter and 3500 to the Great Falls plant.

For January, February, March, April and May the Butte production was 139,555,250 pounds of copper. During May the Boston & Montana Co. averaged 196,000 pounds a day; the Anaconda, Parrot, Washoe, Trenton and Butte & Boston, 442,000 a day; United Copper, 130,000 pounds; Clark mines, 117,000, and North Butte, 35,000.—The Parrot mine of the Amalgamated Company, which was shut down during a part of May and April, is again working to near full capacity and is shipping about 500 tons of ore a day to the Washoe smelter.

While the mine was shut down more men were put to work in some of the other Amalgamated mines and the output increased so that the loss from the Parrot was offset and the production was not affected. The Rarus mine, of the United Copper, which was shut down for some time while repairs were being made on its shaft, is also working a full force again.—B. B. Thayer, assistant to President Rogers of the Amalgamated Company, has been in Butte inspecting the mines and smelters of the company in Montana.—The Reins Copper Co. has authorized the expenditure of \$10,000 a month for six months to develop the Combination mine. It is proposed to sink the shaft 500 feet deeper and enlarge it, and purchase a new hoisting plant and a pump large enough to handle the heavy inflow of water. No cross-cutting will be done until the shaft reaches a depth of 1200 feet, but a station will be cut at the end of each 100 feet.

#### NEVADA.

##### Esmeralda County.

Upon the completion of the line for the transmission of current from Bishop, Cal., to Goldfield, the Combination mine and mill will be equipped with electrical motive power. It is expected that the line will be completed by September 1 next, and it is probable that the various other big properties will also be operated by like power.

##### Lincoln County.

The Gold Bug claims, 12 miles from Caliente and 2 miles north of the Salt Lake Route, are being developed by Caliente people.—South of Caliente deposits of borax have been located by E. Keate and associates.—Geo. Fischer and M. Daly, owners of the Fire Fly claims northwest from Caliente, have bonded them for \$40,000 to Chea, McCornick & Weaver of Cincinnati.—The new cyanide mill on the Abe Lincoln, at Pioche, is in steady operation and making good recovery from the tailings. The concentrator is running on crude ore.

The Quartette mine at Searchlight has commenced regular shipments of ore taken from the lower levels in development work.—T. Gahagan will sink a shaft to water level on the Blackhawk group at Searchlight.—C. Kirkeby has secured the Battle Creek claim, near Searchlight.—The Searchlight mine of the Duplex Co. of Searchlight has been unwatered, the water being used in milling. A promising vein in the lower level is to be developed.—W. F. Smith, J. W. Daulton and G. J. Strodeloff, all of Los Angeles, will form a company to work the Ophir group, near Searchlight.—Manager B. Macready will start development work on the Santa Fe at Searchlight. A small force has been drifting both ways on the 100-foot level.—The Gold Coin Co., sinking on the Sazerac mine at Dupont, expect to reach the 200-foot level by July 1.—The stamps of the new O'Connor mill at Juniper Camp have commenced falling on ore from the Chiquita mine, 1 mile west of the camp.—The Pittsburg group, 1½ mile north of the Wall Street at Eldorado Canyon, has been sold by A. E. S. Price to A. M. Jones of Los Angeles and A. Taylor of Chicago. The deal was put through by J. Howe and he will have charge of shaft work on the claims.

#### NEW MEXICO.

##### Grant County.

The Alessandro Copper M. Co. intend to develop the Victoria and Gettysburg mines near Silver City. P. McQuaid will succeed L. P. Deming as manager. The shaft on the Gettysburg, now down 250 feet, is to be sunk to the 500-foot level; the tunnel on the Victoria, now 400 feet, is to be continued. The 50-ton concentrating plant will be completed.—The Beck mine at Stein's Pass is sacking its telluride ore in the mine without treatment. The lower grade ore is being milled. New tables are being put in and after this work is completed the mill will be worked day and night.—F. G. Burns has taken charge of the work on the Wildcat mine at Santa Rita.—The Nevada M. Co., operating at Santa Rita, has changed its name to the Hermosa Copper Co. J. W. Bihle is superintendent.

#### OREGON.

##### Baker County.

The Connor Creek mine, bonded by P. Basche of Baker City, is to have a new 10-stamp mill, which will be put up below the site of the old 35-stamp mill.

At Baker City, in the case of A. P. Watson vs. The Keystone-Belle & Gold Boy Con. G. M. Co., judgment has been rendered in favor of plaintiff, restoring to him title to the Keystone and Belle quartz claims, which were sold under contract to defendants several years ago. Watson alleged that the terms of the contract were never complied with and sued to have the deed to the claims canceled.—H. T. Hendryx has formed the Taber Fraction M. Co. to work the Taber Fraction mine at Bourne.

##### Grant County.

Manager C. J. Allen will sink another 100 feet on the Monumental mine, near Granite.

##### Josephine County.

A 10-stamp mill is to be put in at the Michigan mine at Michigan City, 1 mile from Murphy. The mill is to be 2600 feet from Applegate creek and 265 feet above it. The shaft has been sunk 120 feet and a drift run 70 feet from that level. Sinking is to be resumed for another 100 feet.—J. C. Mattison, manager of the Copper Eagle M. Co., on Peavine mountain, west of Galice, states that the tunnel is in 300 feet. If the ore holds its high values shipments will be made to the Tacoma smelter. The wagon road from Leland now reaches within 3 miles of the mine, and the work of extending it to the mine will be begun this month.—The Mount Reuben Mining Association will begin operations in the Mount Reuben district, near Grants Pass.—A. F. Hooper plans to put in a 5-stamp mill at the Mount Pitt mine on Jump-off-Joe creek, near Grants Pass. A. Howland has charge of work in the mine.

##### Lane County.

(Special Correspondence).—At the Crystal Con. property in Bohemia the new 5-stamp mill commenced grinding ore on the 10th. The concentrators are not working well and some changes will be made. It is said

that a new and rich ledge has been found on the Twin Rocks property, in Bohemia.  
Cottage Grove, June 13.

## SOUTH DAKOTA.

### Pennington County.

The Clara Bell M. Co. is about to transfer its control to Cleveland, O., people. F. Hebert, the original locator of the property, is to receive \$25,000 the latter part of this month, and will receive for the next two years 7% on \$200,000, and at the end of two years will receive \$100,000 in money. For this consideration he gives up the control of the company. Under the new management it will operate on an extensive scale and a much larger mill will be built. The steam hoist of the plant recently burned, but it has been replaced by Cleveland capital. The mine is located 5 miles southeast of Hill City.

## UTAH.

### Junib County.

The Gold Blossom mine in the North Tintic district, owned by American Fork parties, has closed down. R. E. Hunter of the Capital G. & S. M. Co. states that the shut-down was due entirely to the scarcity of water in that section, the transporting of which by improvised means was expensive. It is the intention to wait until fall, when there will be plenty of water. The company has 4000 tons of ore which is available for shipment. Retimbering the main shaft in the Lower Mammoth of Tintic has reached the 1400 level and sinking will be resumed.

### Salt Lake County.

The Rod Wing air compressor at Bingham has started up. Tunnel No. 3 has been run over 700 feet and has cut two veins, one 25 feet wide, which carries large bodies of milling ore. This will be treated at a mill which the company intends to build. Regular ore shipments, averaging a car a week, are being sent from the McCann raise. The Julian tunnel is in 400 feet. P. M. McCree is superintendent. The machinery at the Butler mine has been started. Connections have been made between the shaft and the Hart tunnel. Regarding Bingham mining conditions, the Bulletin says that in Bingham ores can be mined and milled, the concentrates smelted and the metal product marketed at a total cost of \$1.78 per ton, and a 10,000-ton mill can handle ores carrying but \$3 in values at a profit of \$12,500 daily. Ore carrying but 1% copper can be made to pay expenses, with copper at 10 cents per pound. The same conditions exist with reference to the smelting ores, which produce copper at a total cost of 5 cents per pound. H. Greene of the Bingham Con. Co. reports that the Dalton & Lark ore bodies at Bingham have improved with depth. The new channel opened up in the Lark lode off the main tunnel has been opened up on the strike for over 400 feet and exposed in the face of the east drift 5 feet of ore, which shows good values in lead. This ore is sent to the furnaces of the American S. & R. Co. A raise is being made to connect with the upper workings, but the heavy flow of water is rendering this work slow.

### Summit County.

(Special Correspondence).—The Kearns-Keith mill at Park City, above the Silver King, has a daily capacity of 150 tons. One shift is working at present. Development work is being pushed in the mine. J. T. Kessel is mill foreman. It is understood that the Kearns-Keith Co. intend putting up a large concentrating plant near Park City to handle ore from their various properties. The Ontario mine is cleaning out the drain tunnel, which had a cave-in recently. On account of the cave-in in the tunnel the water has raised to the 1200 level, and it is feared unless they get the tunnel in operation that the water problem in Park City district will be a serious matter. The shaft buildings of the Ontario, which were burned one year ago, have been replaced by new ones. Over the hill from the Ontario the Daly-West Co. is mining 500 tons per day and milling 400 tons. All the first-class ore comes from the upper levels, i. e., above the 1200 level. The 1200-foot level connects with the loading station. The first-class, or shipping ore, is dropped through chutes from the 900 to the 1200, where it is loaded for shipment. The concentrates from the mill are lowered at the shaft and loaded at the mouth of the tunnel in the same manner as the ore. The company are operating with 295 men. J. A. McCaskell is superintendent of the mine and F. W. Sherman mill superintendent. Down the gulch from the Daly-West, the American Flag mine is putting in a new hoisting plant and steel head frame.

Park City, June 12.

The Columbus M. Co. has called for bids to run a 400-foot tunnel at its property in the Elkhorn district, near Park City.

### Tooele County.

Work has been started at the Eureka mine in Dry canyon, near Ophir, under the direction of J. W. Cairns.

### Utah County.

It is reported that the Bazook M. Co. is to resume work near Bingham. A. Van Patten of Salt Lake City is manager.

## WASHINGTON.

### King County.

It is reported that a tin smelter will be built in Seattle, according to a statement made by J. E. Burton of Milwaukee, Wis., president of the United States Alaskan Tin Mining Co. C. B. Russell, in the Marion building, Seattle, has guaranteed the erection of the smelter, providing the Alaskan tin men will guarantee to send their concentrates there.

### Snohomish County.

President M. Mitchell of the Smuggler G. & C. M. Co. states that the main crosscut being driven on the company's property near Index is in 243 feet. Many veins have been cut. On the Sultan river a ditch is being opened across a bar, 4 miles from Sultan, to turn the course of the stream and thereby expose the bed of the river, which will be worked by placer miners. A contract will be let for driving the lower tunnel of the Crown Imperial mine, near Silverton, 75 feet. The tunnel is in 440 feet. The company has received a good re-

port on the property from C. F. Lee. J. Norman is interested in the property. The upper and lower sections of the surface tram at the Sydney mine at Monto Cristo have been connected with a chute 100 feet long and ore is being shipped to the Everett smelter.

### Stevens County.

At the Napoleon mine, near Colville, preparations are being made for steady operations. Ore hunkers have been built, also bunk house, boarding house, etc., and a wagon road is being built from the mine to the nearest railway point. To cross Kettle river the Orient ferry boat will be used temporarily. Ore will be shipped to Greenwood smelter.

## WYOMING.

### Wood County.

An important copper strike has been reported by J. B. Hassett, manager of the Charter Oak M. Co. in the Charter Oak mine, near Saratoga.

## FOREIGN.

### CANADA.

### BRITISH COLUMBIA.

#### Boundary District.

J. Sullivan of Eholt is sinking a prospect shaft on the Granite Mountain claim on Eholt creek. The ore body has been struck on the McKinley, in Franklin camp, at a depth of 100 feet in the long tunnel. W. Hanna and J. Johnson have completed their contract of a 200-foot tunnel on the Golconda in south Deadwood. Another contract of 200 feet has been let by the owners. Shipments from the Boundary mines for the week ending June 10 were: Granby mines to Granby smelter, 11,027 tons; Mother lode to British Columbia copper smelter, 3510; Mountain Rose to British Columbia copper smelter, 132; Oro Denoro to Granby smelter, 132; Emma to Nelson smelter, 132. Total for week, 14,943; for year to date, 410,292. Boundary smelters treated as follows: Granby smelter, 11,195; British Columbia copper smelter, 4040. Total for week, 15,235 tons; total for year to date, 420,274. The May production of the Boundary mines in tons was: Granby mines, 55,420; Mother lode, 13,600; Brooklyn, 7002; Rawhide, 2110; Mountain Rose, 485; Dominion C. Co., 410; Oro Denoro, 387; Emma, 278; Providence, 40; Skylark, 50; Last Chance, 207; miscellaneous, 75. Total, 80,044.

#### East Kootenay District.

Operations at the Sullivan mine on Sullivan hill, on Mark creek, near Fort Steele, have resumed with thirty men. The new compressor and boilers have been put in and twelve drills are in operation. Daily shipments of about 125 tons are made to the Marysville smelter, which is in active operation. It is treating sixty to seventy tons of ore and roasting 100 tons daily. The daily product of the smelter is 100 pounds of bullion. The Perry Creek Hydraulic M. Co. has two 6-inch giants in operation and are working two shifts. Manager R. R. Bruce of the Paradise mine, on Spring creek, near Pinehurst, has started work on No. 4 tunnel, which is in 615 feet. More men have been put to work on the Delphine, near Wilmer. All the ore brought down to the road last winter is now being shipped by steamer to Golden, thence by rail to the smelter. It is reported that the Ptarmigan mine is to resume operations.

## MEXICO.

### Chihuahua.

By November 1 active work will be commenced on a 200-ton addition to the smelting plant of the Encinillas, Mines, Ltd., at Santa Rosalia, according to C. O. Greenwell, who states that although the present plant is used in treating ores from the mines of the company, yet as soon as the pending enlargements have been made the plant will be a custom one.

J. J. Clague has taken charge of the operations on the San Martin silver mine at Urachic. The recent purchaser, J. J. Watterson, expects to leave soon for Denver, Colo., to arrange for the purchase of machinery for reduction works, the kind yet to be determined upon.

G. C. Carothers, W. S. Dillon, general manager of the American-Mexico M. & D. Co. of San Lorenzo, Mr. Ryden, superintendent of the same company, and J. G. Daley, all of Torreón, with W. O. Watson, have organized the Fifth of May M. Co., to operate the Cinco de Mayo properties in the Mapimi district. The property consists of ninety-six pertenencias of entirely new ground.

### Coahuila.

The Constancia M. Co., composed of Saltillo people, is shipping 4000 tons of ore from its properties in Sierra Mojada. It is operating two of its ten mines and has several properties leased to others. W. Hagemann is general manager.

The Continental Copper Co. propose to build a reduction plant at the Panuco mine, near Monclova. O. Wahrmond and M. Koehler of San Antonio, Tex., and S. D. Bridge of Monterey, Nuevo Leon, are interested.

### Durango.

Preparations are being made by J. A. Soram of Boston for the erection of a 250-ton concentrating plant at Guanacavi to work the ores from his Nueva Australia, Soto and other mines on the Soto vein, in the Guanacavi district. A matting furnace will be put in and the concentrates and high-grade ores will be converted into matte.

### Puebla.

The Cia. Minera de Mexico, Ltd., has started its new 150-ton chlorination and cyanide plant at Tatales. The company is said to have 80,000 tons of manganese ores, carrying gold, in sight.

### Guerrero.

(Special Correspondence).—S. L. Butler, president of the Pioneer Sampling Co. of Salt Lake City, Utah, has denounced with the name of Los Pozos ten pertenencias in the Los Pozos basin and is developing a contact vein between slate and porphyry. Near the hacienda of the Concepcion he has denounced and is working fifty pertenencias called the San Pabito. The Babylonía mine, near the Arroyo de la Naranjitos in the Los Pozos basin, is being worked under the management of Horacio Lopez. C. Castillo has denounced 150 pertenencias

running from the Los Pozos basin southwest to the Rio de Chata. The Carrizal mill will resume work on the ore in the bins. In the mine work has been suspended except in the main shaft. Near the Rancho La Mira 2000 pertenencias of iron ground have been denounced by the Pacific Steel Co.  
La Union, June 4.

### Sonora.

The Alsacia M. Co. is to resume operations at its property, 28 miles northeast of Cananea, in the Ajo mountains. A small hoist and milling plant will be added. C. F. Wren of Bisbee is general manager and J. Herman of Globe is consulting engineer.

In the Moctezuma district the reverberatory furnace recently put in by the Transvaal M. Co., near Campas, is running continuously and turning out matte. The ores treated are high grade, averaging 20% copper. The same company are now building a silver-lead furnace, which will be ready to blow in about July 1. At Alamos the Zambona D. & M. Co. are pushing work upon the Minas Nuevas group. W. S. Cranz and A. Yaeger of Nogales are at the mine in charge of work.

A mill with a daily capacity of 500 tons of ore is to be built by the Red Mountain M. Co. at the Cerro Colorado mines, in the Altar district. A pumping plant and pipe line will be built, to carry the water 6 miles to the mill. G. E. Earnshaw is general manager at the mine.

### Zacatecas.

R. G. Gemmel of Salt Lake City, Utah, has been making tests on the ore from the mine of the Santa Rosa de Mazapil M. Co., at Mazapil, with a view to putting in a mill to handle the second-class product. Ore from development work is being shipped to the smelters.

## Books Received.

The engineering profession usually welcomes the writings of one of their number as a distinct aid to the advance of engineering work. Prof. Frank Soule of the University of California has kindly written the accompanying review of Prof. John Lyle Harrington's compilation of "The Principal Professional Papers of Dr. J. A. L. Waddell." Dr. Waddell has received the honorary degrees of Doctor of Science from McGill University, Canada, and Doctor of Laws from the University of Missouri, as well as his professional C. E. from Rensselaer Polytechnic Institute. He is one of the best known engineers and professors of civil engineering in the United States. He is a member of the American Society of Civil Engineers, of the Rensselaer Society of Engineers, of La Societe des Ingenieurs Civils, of the Canadian Society of Civil Engineers, of the Japanese Engineering Society (Kogaku Kyukai), and other organizations. It is easy to be understood, therefore, that with his lifelong devotion to the teaching and practice of his profession, and his ripe experience, his professional papers and publications should command the interest and attention, not only of students and engineers, but of the general reading public. One of the most interesting papers in this book is entitled "Civil Engineering Education," and is accompanied by comments from Prof. Wm. H. Burr, head of the department of civil engineering in Columbia University, Prof. A. J. DuBois of Yale University, Prof. Geo. F. Swain of the Massachusetts Institute of Technology, Alfred P. Beller, C. E., G. Bouscaron, C. E., W. H. Booth and many others. The discussions by these eminent men, as recorded in this work, add greatly to the interest in the original papers drawing forth their remarks. Mr. Harrington has done a good work in collecting these scattered papers and giving them to the world in a form alike pleasing and instructive to the engineer and the general student in these lines. His introductory notes form the connecting links that make the book a continuous treatise on civil engineering, and while he does not hesitate at times to differ somewhat from Dr. Waddell's views on general questions—as, for instance, on the ideal education of the civil engineer—yet his sympathetic and intelligent handling of the material composing the work adds greatly to its value. The language is clear, simple and direct, free from technicalities and instructive as an example of business and professional English. It could hardly be otherwise, since the book contains examples of the writings of fully 100 engineers and professors of engineering. As the list of names contains those of many of the most prominent technists in America, and their discussion of Dr. Waddell's papers, it is perhaps the more remarkable that the book should be so free from language unintelligible to the ordinary reader. Dr. Waddell's paper on "Civil Engineering Education" is fully and freely discussed not only by the editor, Mr. Harrington, but by Profs. Burr, DuBois and others, who agree that the education of the civil engineer should be founded upon a broad and liberal culture. This and many other chapters are of general interest, bearing on broad and general questions; but the work is especially valuable to engineers, because it deals with many practical problems such as daily confront the man in the field, or the designer in his office; and also to the young engineer just starting out in his career, treating, as it does, in great detail, the various subjects discussed. Dr. Waddell emphasizes the fact that the science of the engineer consists in adapting means to an end in using the materials on the ground to the best possible advantage and with the least practical cost. Any engineer can build a bridge, lay a foundation, drain a swamp, provided all materials are furnished. The problem then becomes merely a matter of computation and cost. But engineering work is rarely conducted with ideal conditions, and the skill of the engineer is shown in overcoming natural difficulties, or in forcing them to become aids to his work. The papers in this volume were written by a man who came to his desk from his triumphs in the field. He tells us of real and difficult problems solved, of formidable obstacles overcome; and he gives abundant advice, practical in its nature, rather than simply theoretical. He lays much stress on the drainage of land, a subject on which too little has been written. The first chapter in the book entitled "Railroad Drainage," although writ-

ten in 1878, is as instructive to-day as when it was published—that is, shortly after Dr. Waddell had completed a term of service in the construction of that portion of the Canadian Pacific Railway lying northwest of Lake Superior. His various papers on engineering problems in Japan are due to the fact that Dr. Waddell was, for several years, Professor of Civil Engineering in the Imperial University of Tokio. They will be of interest to the general reader as well as to the engineer, since they show, incidentally, the engineering conditions in Japan twenty years ago. His advice to young Japanese engineers might well be impressed to-day on every class graduating in civil engineering from our home institutions. The papers following this, with the exception of one on the advisability of instructing engineering students in the history of the engineering profession, are more technical in character, and are illustrated with maps, charts and drawings bearing on specific engineering problems. The engineer will read with profit and interest the chapters on "Railway Bridge Designing," the "Compromise Standard System," "Safe Working Stresses," "Elevated Railroads," "Foundations" (relating to work done in the City of Mexico), and several others. The special attention of the reader is called to pages 29-61 (Railroading); 211-453 (Bridges); 589-779 (Elevated Railroads), with full discussions by eminent engineers; and 785 to the end of the work, embodying his addresses on engineering educations and also technical dissertations. The volume cannot fail to be instructive and interesting, both to students and practical engineers, and will certainly be a valuable addition to the library of each of these classes of readers. Published, 1905, by Virgil H. Hewes, 245 West 107th street, New York City.

## Trade Treatises.

Excavating and screening outfits are portrayed in a leaflet from the Jeffrey Mfg. Co. of Columbus, O.

The Jeffrey Mfg. Co. of Columbus, Ohio, sends an illustrated description of the Jeffrey swing hammer, crusher and pulverizer and of the Jeffrey roll crusher.

The current number of "The Valve World," published by the Crane Co., Chicago, Ill., is devoted almost exclusively to Lewis & Clarke Centennial Exposition, now in progress at Portland, Or.

The July issue of Air Power, a technical quarterly devoted to compressed air and its uses, published by the Rand Drill Co., contains an illustrated description of a displacement pump, written by Prof. E. G. Harris; a description of a recent installation of a compressed air mine haulage system, by A. A. Bowman, M. E.; "The Uses of Compressed Air in the Wood Working Shop," by W. R. Hulbert, M. E.; a description of the construction of the new Duluth aerial bridge; an article on the Philadelphia high pressure pumping plant; a practical article on "Air Compressor Foundations," by E. M. Mackie, M. E.; three new inventions, as follows—a new tunneling machine, a pneumatic stake driver (used by Barnum & Bailey) and a device for conveying hot rivets through a metal tube by compressed air.

## Commercial Paragraphs.

THE Compressed Air Machinery Co., 24-26 First St., San Francisco, Cal., are finishing a large compressor for the Murchie mine, Nevada City, Cal.

J. W. DUNTLEY, president Chicago Pneumatic Tool Co., has returned to Chicago, Ill., from Europe, where he purchased the factory and business of E. G. Eckstein, Berlin, Germany, and that of the Lencke Co., St. Petersburg, Russia.

THE S. H. Supply Co. of Denver, Colo., are furnishing a No. 54 Lidgerwood single-cylinder hoist, with necessary hoiler capacity, cable, ore buckets, etc., to the Lodi M. Co. at Austin, Nev. The Lidgerwood Mfg. Co. have placed their Western agency with this company and are making a special mine hoisting engine for this market.

A CONNECTION of the Ingersoll-Sergeant Co. and the Rand Drill Co. has been made through the incorporation of the Ingersoll-Rand Co. under the laws of New Jersey. The new company will have a capital stock of \$10,000,000 and will manufacture air compressors, mining and quarrying machinery and pneumatic tubes as well as drills.

## Obituary.

J. W. McCULLY, owning mines at Payette lake, and a pioneer of Weiser, Idaho, died there June 3, aged 71 years.

D. C. HAIG, a mining engineer and millwright, died June 7 at Hypollite, Nev. He was a native of New York and 56 years of age.

G. N. B. McLEAN, formerly superintendent Detroit C. M. Co., and interested in Morenci, Ariz., mines, died at Los Angeles, Cal., June 6, from accidental poisoning.

T. W. BOGGS, a pioneer mining man of Arizona, was killed June 7 by being thrown from a buggy near Arizona City. He owned valuable mines in the Big Bug district.

EDWIN WILLIAMS, the Challis assayer, and Western pioneer, died suddenly from heart trouble near the head of Darling creek, north of Challis, Idaho, May 24, aged 56 years.

## Latest Market Reports.

SAN FRANCISCO, June 16, 1905.  
METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, har silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, \$15.00; Lake, 1 to 3 casks, \$15.00@15.25; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.25@14.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £66 spot per ton.

The copper market shows a slight fall in prices from last week, but these minor changes are due wholly to the ordinary fluctuations in trade, and do not represent the industrial conditions as related to the production and consumption of copper.

Following are the figures of the German consumption of foreign copper for the months of January-April, 1905.

	1905.	1904.	1903.
Imports, tons.....	33,172	40,859	27,363
Exports, tons.....	4,413	2,651	8,833
Consumption, tons.....	27,759	38,208	23,427

Out of the above, 26,720 tons were imported from the United States.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £13 long ton.

SPELTER.—New York, \$5.35; St. Louis, \$5.70; London, £24 long ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.20; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 34½c, 35@37½c. London, £137 17s 6d.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, 50c; dust, 40c; 10c; sulphate, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99½ pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99½, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.35; gray forge, \$16.00; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@23.00; open hearth billets, \$23.00@23.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price.

Dry Lead.—In hbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per hhl. CEMENT.—Imported, \$2.15@2.65 per hhl.; California, carload lots, \$1.90 f. o. h. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to hhl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.50; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in hulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2\*, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron,

8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, hulled, hbl., 62c; cs., 67c; raw, hbl., 60c; cs., 65c; Lucol oil, hulled, hbl., 54c; cs., 59c; raw-hbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 18c; As-tral, 18c; Star, 18c; Extra Star, 21c; Eocene, 20c; Elaine, 26c; Water White, in hulk, 11½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, hulk, 15½c; do., cs., 22c; 86° Gasoline, hulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in hulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., hbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 53@65c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, 80c.

URANIUM.—Oxide, 80c.

MERCURY.—Bichloride, 80c.

TUNGSTEN.—Best, 80c.

PHOSPHORUS.—American, 70c.

SODIUM.—Metal, 60c.

BISMUTH.—Subnitrate, 80c.

SILVER.—Chloride, per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, 1 ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

HORSE BLANKET.—No. 701,372. May 30, 1905. Reuben A. Seaders, San Francisco, Cal. The object of this invention is to provide a blanket which is cheap and easily constructed, and it only requires the cutting of the material from the piece into the desired lengths, which are then stitched together and the blanket thus completed. It consists in the formation of a blanket by a union of sections stitched together and folded so as to produce the desired shape without cutting the material except to cut it into the proper lengths for the purpose.

STONE SAW.—No. 791,157. May 30, 1905. Archibald H. MacNutt, San Francisco, Cal. This invention relates to improvements in blades which are designed for sawing granite, marble, stone, or other material where abrasives are employed. It consists in the construction of the saw in such a manner that the abrasive material used in conjunction therewith will be constantly fed beneath the edge of the saw to produce the greatest downward and the least lateral cutting consistent with good work. The device comprises an abrasive saw having openings made at intervals in its lower edge, said openings being divergent from the top downwardly and having their walls diagonal relative to the line of travel of the saw.

DREDGER BUCKET.—No. 791,700. June 6, 1905. John J. King, San Francisco, Cal. This invention relates to improvements in buckets which are designed for use upon dredgers. It consists in the formation of the tail or lower end of the bucket continuous and integral with the sides and without joint at the junction of these parts.

DINING TABLE OR COUNTER.—No. 791,708. June 6, 1905. Nicholas N. S. Matcovitch, Oakland, Cal. This invention relates to improvements in dining tables and counters for restaurants, hotels, eating stations and the like, especially in localities where it is very cold at certain seasons of the year. Its object is to provide suitable d h warming means in conjunction with a table or counter, so that plates, platters, side dishes, etc., containing viands which should be served hot may be maintained in heated condition indefinitely after being placed before the diner. The device comprises a lunch counter or table, of a revolvable center stand including a base, a pedestal supported thereon, and supports on the pedestal provided with locally heated areas.

POWER FRUIT PRESS.—No. 791,746. June 6, 1905. Harvey M. Barngrover, San Jose, Cal. This invention relates to an apparatus which is designed for the compressing of dried fruits into boxes or packages. It consists in the combination of mechanism whereby the boxes containing a given weight of fruit are advanced, placed beneath the press, and the mechanism automatically returned after the pressing of each box is complete.

SPRING DANCING FLOOR.—No. 791,792. June 6, 1905. Richard E. Jeffery, Grass Valley, Cal. The object of this invention is to provide an elastic floor for any purpose for which such floor may be required. Such floors are very desirable in halls where dancing takes place. This invention comprises an elastic floor, consisting of boards laid closely to form a surface, other boards laid transversely intermediate of and parallel with rigid supporting joists, and supports extend between the joists to which the second boards are secured.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JUNE 6, 1905.

791,746.—FRUIT PRESS.—H. M. Barngrover, San Jose, Cal.  
791,864.—RULE HOLDER.—W. O. Bell, Los Angeles, Cal.  
791,861.—DUST BRUSH.—H. T. Epperson, S. F.  
791,617.—OIL BURNER.—M. A. Fesler, Visalia, Cal.  
791,463.—MUSIC RACK.—O. G. Gordon, Eureka, Cal.  
791,623.—HOE.—A. Holmes, Milwaukie, Or.  
791,786.—BALCONY.—F. C. Hotchkiss, Los Angeles, Cal.  
791,910.—CAR STEP.—E. Howe, Everett, Wash.  
791,792.—DANCING FLOOR.—R. E. Jeffery, Grass Valley, Cal.  
791,700.—DREDGER BUCKET.—J. J. King, S. F.  
791,528.—SIPHOON BOTTLE.—D. Landau, S. F.  
791,706.—MANIFOLD BOOK.—A. Levison, S. F.  
791,708.—DINING TABLE.—N. S. Matcovitch, Oakland, Cal.  
791,933.—ANIMAL TRAP.—W. McEndree, Fullerton, Cal.  
791,642.—FREIGHT CAR.—J. A. McGhie, Everett, Wash.  
791,805.—FISHING REEL.—G. Michellish, Avalon, Cal.  
791,567.—BARREL CLEANER.—A. E. Moorhead, E. Market, Cal.  
791,731.—CONCRETE MOTOR.—F. J. Morgan, Nevada City, Cal.  
791,715.—DRAFT EQUALIZER.—I. N. Noyer, Pomeroy, Wash.  
791,721.—OIL BURNER.—J. Palmatary, Los Angeles, Cal.  
791,812.—OIL BURNER.—J. Palmatary, Los Angeles, Cal.  
791,814.—WRENCH.—W. M. Pitzer, S. F.  
791,496.—CREAM SEPARATOR.—A. Porten, Berkeley, Cal.  
791,650.—FRUIT PITZER.—K. T. Elbert, San Jose, Cal.  
791,577.—SUBMERSE ORE.—E. Riveroll, Los Angeles, Cal.  
791,528.—DRIER.—W. F. Robinson, Anacondes, Wash.  
791,502.—VEHICLE WHEEL.—A. H. Rochford, Point Reyes, Cal.  
791,651.—WRENCH.—J. Roemer, Santa Maria, Cal.  
791,517.—SMOKE CONSUMER.—S. M. Walker, Los Angeles, Cal.  
791,596.—ROTARY MOTOR.—O. E. Waxed, Oakland, Cal.  
791,970.—SASH HOLDER.—A. Wilkie, S. F.  
791,654.—PUMP.—E. J. Wilson, Southend, Wash.  
791,666.—PLUMBING.—J. M. Wishart, Pasadena, Cal.

## An Important Mining Region.

One of the most important mining districts of the West is that about Park City, Utah. Of the several mines of that locality the Ontario is the best known. The history of this great mine is interesting.

The first mine in this part of Utah was the Miller mine at the head of American Fork canyon. Other noted mines of those early days were the Emma and Flagstaff at the head of Little Cottonwood canyon. While these mines were producing their millions in lead and silver, but scant attention was given the region about Park City. The location is near the summit of the Wasatch range, 25 miles southeast of Salt Lake City, and 3000 feet above it, the elevation above sea level being 7200 feet. Park City is on the east slope of the range, which is far less rugged than that on the west. The Wasatch is formed by the faulting and uplift of a great block of limestones, quartzites and other sedimentary rocks, which have been intruded by igneous rocks of various kinds. The west slope of the mountains is very steep, being the scarp of the uplift modified somewhat by subsequent erosion. The Park City district lies between the rugged bluffs that mark the crest of the main range and the rolling slopes and meadows of the eastern foothills. The altitude of this region results in rather short cool summers and autumns, with long

Buildings and Dumps, Ontario Mine, Park City, Utah. (See Page 407.)

cold winters, during which the snowfall is heavy, and the temperature averages low.

The Wabash Mine, Near the Ontario, Park City, Utah. (See Page 407.)

The Daly West Mine, Park City, Utah. (See Page 407.)

The accompanying illustrations give an excellent idea of midwinter in this part of the Wasatch, and also its appearance late in the spring, when the greater part of the snow has disappeared, but considerable still remains on the north slopes, where the drifts have been deep.

The Ontario mine was discovered in June, 1872. The outcrop was small, projecting but an inch or two, and was mostly covered by detritus. With a width of 18 inches at the surface it pinched to 8 inches in sinking 8 feet, which was not very encouraging for prospectors in that region, even though the ore assayed 100 to 400 ounces per ton. The prospect was sold within sixty days of its discovery to George Hearst and others for \$30,000 through Marcus Daly, who negotiated the transaction.

An active campaign of development was at once started and the mine improved, but there were times in its history when the future looked anything but promising. Great floods of water was one of the disadvantages, and it is said that at one period an unavailing effort was made to sell the property for about \$300,000. The mine was opened through tunnels driven from the neighboring gulch, and eventually three shafts were sunk, the deepest being over 2000 feet. One of the great features of mining at the Ontario was the drain tunnels, the longest of which is several thousand feet. The mine has produced silver which sold for more than \$35,000,000.

The active development of the Ontario stimulated prospecting throughout the district, and the Ontario fissure was traced westward into the Daly, Daly-West and Daly-Judge mines, all of which have developed into valuable properties. Within eight years after the discovery of the Ontario over 1200 claims were located in the Uinta district, where these mines are situated.

The fall in the market value of silver seriously affected the mines of the district for a time, but changes and improvements were made in mining and metallurgical methods, and although silver continued to fall still lower, the price of lead advanced somewhat, and the mines were again able to operate at a profit. The ores contain chiefly silver, lead, copper and gold, their importance being indicated by the relative position of the metals named.

There are ten shafts in the district varying in depth from 1000 to 2000 feet, the deepest starting at a lower point than any of the others. There are four drainage and transportation tunnels, the longest over 3 miles. Mining and metallurgical operations are thoroughly modern. Some of the metallurgical operations have been previously described herein, notably the concentration of slimes by F. W. Sherman.

THE index to the volume ending with to-day's issue will be found on pages 416, 417, 418, 419 and 420, and is an exponent of the wealth and variety of this journal's contents. In response to numerous requests, an innovation is made in indexing "Concentrates," a separate section being devoted thereto. The contents of this journal for the six months ending to-day comprise all that is of most present importance in the great mining industry of the country, and, like its eighty-nine predecessors, exemplifies "the present state of the art."

THE theory of the formation of the diamond is again being given considerable attention by various scientific writers. This question has been the subject of careful investigation for many years, and at various times prominent writers on scientific subjects have expressed the opinion that the mystery of the formation of the diamond had been solved, and as often other observers, whose opinions are entitled to as much consideration, have shown that these conclusions were based on unsubstantial premises. Gardner F. Williams, whose opportunities for intelligent observation in this direction have been superior to all others, candidly confesses he is unable to account for the remarkable occurrence of diamonds in the volcanic pipes of South Africa.

SOME chemists and practical operators who are making a specialty of the cyanide process have suggested that cyanide operators generally are "getting in a rut," and that greater things and further improvements are possibilities of the future. Doubtless this optimistic prophecy is not without foundation, and the cyaniding fraternity will gladly welcome any improvement or modification of the process which will cheapen the operation and make a higher extraction and recovery possible. It seems that much remains to be desired in the precipitation of the dissolved gold—something superior to the zinc precipitation with its various modifications. New facts concerning cyanide operation are being learned with surprising frequency, and the prophets of better methods and more satisfactory returns predict not without reason.

## Measure of Efficiency in Mine Management.

A comparison of mining costs is not always just, for the reason that conditions under which these costs were made may be so totally different as to afford no fair means of comparison. Working costs at a large mine which has been in operation for years, and where the organization has reached a high degree of excellence, may seem astonishingly low to stockholders in a small mine in the development stage where capital is limited. The power plant is small and consequently more expensive per unit of power than that at the large well equipped mine. Water may make in the mine more rapidly than the machinery at hand can readily control. This means increased expense per unit of power. In almost every department expenses for any operation are higher than at the large plant, and those interested in mining should bear this in mind. The fault is not always in the superintendent, but in the home office, which is either unwilling or unable to supply the necessary means to properly equip the mine and to permit the conduct of mining operations on a scale which will reduce the expense account as related to the amount of work accomplished. It is obviously more expensive to work only two or three men per shift underground with a surface crew of four men than to put eight or ten men in the mine while utilizing the same surface crew. The limited means available for the opening of some mines has brought the ingenuity of the superintendents of these mines into active play, and the various devices improvised and applied to the work in hand is instructive and sometimes amusing. At some mines one man at the surface performs all the labor—is engineer, blacksmith, timberman, roustabout, fireman, and sometimes also general manager. This can only be accomplished usually by the employment of devices, more or less unique, which are automatic in their operation and thus take the places of men. While miners below are drilling, the topman becomes timber framer or blacksmith, answers bell calls, looks over his hoisting machinery and gives attention to the general business connected with the mine. When the shots are fired and the miners begin to muck he turns engineer, and hoists the bucket or skips, which dump automatically into a bin or car, lowers the vehicle into the mine, and then goes out and trams the rock to the dump, returning to the engine ready for the next load. His bookkeeping and letter writing are done at night, and he is the busiest man about the establishment. Such a man usually gets from \$100 to \$150 per month. His ingenuity and industry monthly saves the company the wages of an engineer, carpenter and topman, but as a rule it is considered that he has done no more than he should, and on the whole is an extravagant manager, because in working thus from "hand to mouth" his costs are relatively higher than those at a large and well-equipped mine with a staff of engineers and assistants, where money is available for every necessity, and costs can be reduced to a minimum by reason of the large scale of operations.

## Errors in Lode Location.

A Colorado court recently decided that a mining location was invalid because the surveyor employed to survey the claim—presumably for the purpose of making application for patent—had "tied" the claim corners to a rock and tree. The court declared that it was the duty of the locator to tie to a corner of the Government land survey. Such arbitrary decisions from lower courts need not create any alarm, for the Supreme Court of the United States would not invalidate a claim made in good faith, simply because a careless surveyor failed to tie the corners of the location to the land survey. The statute requires that the boundaries be plainly marked, so they may be readily traced, and if a stake at each corner is not visible from the farther corner, other stakes must be placed in intermediate positions. The Federal statute requires (Sec. 2327): "That the description of vein or lode claims upon the surveyed lands shall designate the location of the claim with reference to the lines of the public survey," etc. There has been within the past two years much talk and some litigation over the position of mining claims and the Supreme Court has decided that the monu-

ments control; and if the deputy mineral surveyor made an error in direction or distance in referring the claim to the public land survey, such error does not invalidate the location, and it seems inconceivable that the failure of the surveyor to so connect the claim corners with the land survey—substituting rocks and trees—will not be viewed in the same light by the Supreme Court.

## Sinking Fund for Mines.

Where large improvements are to be made on a mining property, the means to make them must be forthcoming from some source. In many cases this is accomplished by the levy of assessments on the stock of the company; in others it is derived directly from the net output of the mine. The latter is by all means the most satisfactory, and every mine which possesses the elements of commercial success should be so managed that a certain percentage of the net yield may be placed monthly in a sinking fund to be invested in securities, readily negotiable without loss, at any time the money may be required to replace or to extend the plant. When a mine's business is handled in this manner it is approaching the nearest to a legitimate business enterprise; but when these necessities of the concern are made a means of depressing stock values for the purpose of speculation, the proposition presents a somewhat different aspect. The prompt distribution of every dollar of net earnings in the form of dividends may be gratifying for the time being to the stockholders, and the market price of stock is usually favorably influenced to a considerable degree by such disbursements; but when the dividends are reduced, stopped altogether, or, still worse, an assessment is levied to meet the requirements of extensions in plant and the enlargement of the scope of operations, whether such increase will result in ultimate greater economy of production or not, the effect on the stock of the corporation is depressing. There are instances where this short-sighted policy of the management has "method in its madness," which is to be deplored, for the reason that it is these uncertainties in results which tend to place mining among the "hazardous risks" in the commercial world, when the more conservative handling of the mine's business would result in giving to its stock that firmness which characterizes a certain line of substantial industrials.

WHILE innovations, more or less startling, are constantly being introduced into the business of mining and of metallurgy, there are other lines in which equally great, if not more startling, changes are being made and contemplated. These are mostly in engineering and in electricity, or the application of electrical energy to the former. Particularly is this noticeable in transportation. On railways a speed of 60 miles per hour for comparatively short distances, and of 30 miles an hour for long distances, has long been an accomplished fact. Recently an Eastern railway put on an express train which ran from New York to Chicago in 16 hours, or a speed of about 60 miles per hour for nearly 1000 miles, with a much higher speed over a part of the distance—this with steam equipment. Now it is proposed to apply electricity to the transportation problem between these cities, with the assurance that there will be no ultimate difficulty in making the distance in eleven hours, or at the rate of 90 miles an hour. To say that this will not eventually be accomplished would be an unwise assertion.

THE Charters Towers district of Queensland, Australia, produced in 1904 over \$6,000,000 in gold, besides values in other metals. The district is in a semi-desert, where the natural difficulties are abundant and where, for the most part, methods of mining, transportation and reduction are somewhat primitive to say the least, all of which speaks well for the natural resources of the district. This is not an unusual condition. There are many places in the Western United States where the richness of the ore at the surface has in the past and still admits of the most crude methods and an extravagance of management which is unheard of in older well organized mining regions. Notwithstanding the richness of these mines, comparatively small profits are made from their operation owing to this primitive handling.

## CONCENTRATES.

ORDINARILY boilers require about 1 cubic foot of feed water per hour for each nominal horse power.

ORE to be crushed dry must first be subjected to a drying process, which will drive out the moisture, otherwise the ore will have a tendency to pack.

MUCH telluride ore on roasting shows gold. Some auriferous arsenical ores will do the same thing. Arsenical ore cannot be readily amalgamated.

CHINA produces and exports considerable crude antimony and antimony ore. The quicksilver produced in China does not fully supply the local demand.

IRON sulphide is found in greater or less amount in nearly all coal, also in conglomerates and in gravels which have never been consolidated into solid rock.

ANY work done on an unpatented mining claim, whether by day's pay, contract or otherwise, so long as it is performed at the instance of the owner, is chargeable to assessment work.

FROM twenty to thirty gallons of water are required to condense one gallon of water from steam in condensing engines, or approximately 1 to 1½ gallons per minute per indicated horse power.

THE mil is a unit of length in measuring the diameter of a wire, being 0.001 of an inch. It is used in electricity. A circular mil equals the square of the diameter in mills or thousandths of an inch.

REVERBERATORY FURNACES vary greatly in size, from 7x10 feet hearth area to 17x70. The cost depends upon size, material used and its cost, method of construction and price of labor.

ALTHOUGH mining has been carried on for centuries in England and on the continent of Europe, there are many of these old districts where old-time and comparatively primitive methods are still in vogue.

WHEN heated before the blowpipe on charcoal, bismuth and its ores give a dark orange-yellow coating which fades to lemon yellow on cooling—the yellow coating being usually surrounded by a white ring.

JOSEPHINITE is a natural alloy of platinum and nickel, the chief characteristic of which is its marked magnetism. It occurs in grains in the sands of placer deposits in Josephine county, southern Oregon.

UNDOUBTEDLY losses occur in cupellation in the fire assay, but where good cupels are employed and the work done by an experienced operator, the losses by volatilization and absorption are usually so small as to be negligible.

MOLYBDENITE and some varieties of specular iron ore look much alike to the unpracticed eye. They may be distinguished by the superior hardness of the iron ore and its red-brown streak. The streak of molybdenite is black and metallic.

ALASKITE is a silicified aplite, or micaless granite. It is not known as associated with laccoliths. The rocks noted in connection with laccoliths in Arizona, Colorado, Utah, South Dakota and Nevada are usually quartz-porphry, rhyolite, andesite, etc.

TO RENDER a compressed air plant efficient, the pipes and receivers must be of liberal size and inspected frequently in search of leaks, which, when occurring, must be stopped. Flange joints for at least every other section of pipe are advisable in air and water pipe lines.

THE locomotive or fire-box boiler is a convenient but wasteful method of creating power. The return-flue boiler is more expensive in first cost, but is also more economical in operation. The fire-box boiler can be improved by placing a damper in the stack and by utilizing a water heater.

BORAX MINERALS give a greenish color to the blow-pipe flame. Colemanite (calcium borate) exfoliates and fuses imperfectly when heated before the blowpipe. The crystals are monoclinic, but otherwise resemble some calcite. It contains boron trioxide, 50.9; lime, 27.2; water, 21.9.

POCKETS of gold occurring erratically in a vein or in the wall rocks near it are not a proper measure of the value of the ore per ton. Usually in mines producing pockets the vein material is too low grade to mill. There are numerous fortunate exceptions to this condition, for some well known milling mines have produced substantial pockets of gold.

ONE of the most important details requiring attention in the operation of canvas plants for the concentration of slimes is the even distribution of the material at the

head of the table, and another is to see that the tables are not overloaded. Either of these matters, if not properly attended to, will result in inferior work, producing dirty concentrates.

A RULE for calculating the size of pulleys is as follows:  

$$d = \frac{D N}{n}$$

$$n = \frac{D N}{d}$$
 D=diameter of driving pulley; d=diameter of driven pulley; N=revolutions per minute of the driver. n=revolutions per minute of the driven pulley.

AIR COMPRESSORS run by electric power are not uncommon about mines. The air is employed in drilling, running hoists, both above and below ground, and where the receivers are large and the pressure high—100 pounds per square inch—an installation of this character possesses some advantages when applied to hoisting. If the power is suddenly shut off, the air plant has usually sufficient expansive power in reserve to bring the skip to the surface.

THE discovery of tin ore (cassiterite) at Tinton, Lawrence county, South Dakota, is not a new event in mining. Tin was discovered there in 1880, and considerable exploratory work was done during the '80s in the development of the numerous prospects, but it is only within the past year that an effort has been made to reduce the ores at the mines. For this purpose the experimental mill at Tinton was built, and is said to successfully handle the ore.

THE New York Subway starts at the lower end of Manhattan island and runs northerly to 167th street, at the upper end of the island. A branch runs easterly from 103rd street to Westchester, passing beneath Harlem river. It cost \$35,000,000. Its greatest depth is at Fort George. There are elevators for all stations more than 30 feet below the street level. The total length is 21 miles; the height of the subway is 13 feet. Express trains run on this line at 40 miles per hour. The work was commenced March 26, 1900.

THE curvature of the earth is generally calculated at 8 inches for a mile, or, more accurately, .667 foot in 1 mile. This increases as the square of the distance, being four times 8 inches for 2 miles, and nine times 8 inches for 3 miles, etc. This is slightly diminished by the refraction of the atmosphere, which has a tendency to make the object appear higher than it really is, but varies with temperature. Although the discrepancy in level of an object a mile distant is but .572 foot, allowing for curvature and refraction, for 100 miles it is 5717 feet.

THE placers of the Black Hills are derived almost wholly from veins occurring in rocks of Archæan time, the notable exceptions being those resulting from disintegration of gold-bearing conglomerates of the Cambrian period, which originally derived its gold from the Archæan, and the gold derived from certain ore deposits in the Cambrian formation and veins occurring in eruptive rocks which were intruded into the sedimentaries probably as late as the latter part of the Cretaceous. The gold in Two Bit gulch is an illustration of the latter occurrence, and that in Blacktail the former.

AN economical means of hauling timbers from the level up into a raise or stope is sometimes employed in the form of two sheave wheels securely fixed at the top of the raise, two being employed to get the necessary distance between the ropes. An empty bucket is attached and hauled up into the stope. The timber to be raised is then attached to the opposite end of the rope and the bucket filled with ore or with waste and, acting as a counterbalance, the timber is raised to the desired point with a minimum of power. Where large amounts of timber are to be raised, it is advisable to put in a small air or electric hoist, though a still better plan is to put the raise through to the level above and send the timbers down rather than to raise them to where needed.

THE forces which tend to disrupt materials are of several kinds. These are termed stresses. A tensile stress is that force which has a tendency to pull the material (as a stick of timber) apart; compressive stress is the force tending to crush it by pressure upon the ends, as the cap crushing the top of a post; transverse stress is pressure upon the sides, as exhibited in the weight of heavy ground on the cap, which has a tendency to break it in two; torsional stress twists it, as may sometimes be seen when drift sets begin to ride, and shearing stress has a tendency to make one portion of it slide over another, causing splitting and collapse of the support. All of these forces can frequently be observed operating in timbers placed in mines.

THE diameter of the suction pipe of a pump should be such that the velocity of the column of water demanded by the speed of the pump can be easily maintained by the atmospheric pressure, plus any available head on the suction pipe over and above the resistance due to valves and pipes. The suction hose for pumps should be as short as convenient and considerably larger than the discharge column of the pump. The suction hose is wound with steel wire to prevent collapse due to atmospheric pressure, and it also serves in a measure to protect the pipe from damage due to contact with the rocks. The hose should be further protected by winding it with

½ inch to ¾ inch rope. This prevents the rocks in a shaft from cutting the hose, which will quickly happen should the pipe come in contact with the rocks when the pump is in operation.

IN the pulverization of ores it is generally desirable to have the material crushed pass out through a screen as soon as the particles are reduced sufficiently in size to escape, but there are certain ores where this practice would be detrimental to the best results in amalgamating. An ore carrying a large percentage of pyrite or other sulphide mineral, and that in which the gold does not quickly unite with the quicksilver, gives better results if crushed in a mortar having high discharge, and therefore retarding the escape of the pulp from the mortar. This gives the particles of gold an opportunity to amalgamate and settle in the bottom of the mortar or to become attached to the plates inside the mortar, or, if escaping, to adhere to the outside plates. Experience teaches that it is advisable to save gold as early as possible in each stage of the process.

A SLIGHT change of angle in a shaft need not preclude the use of a Cornish pump, nor for that matter in a shaft having sharp changes of angle. In the former case the rod is joined by strong links or side bars, and the ends of the rods are provided with rollers which carry the stress and weight at that point, the link gives the rod a small amount of flexibility and the device enables the pump to be operated without jar and with little "lost motion." Where the change of angle in the shaft is considerable the direction of motion of the two parts of the pump rod is changed by connecting the two ends by "bell cranks," or "bobs"—that is, triangular devices which admit of many different arrangements, whereby the line of motion is changeable from horizontal to vertical or from any given angle to another. Some of these arrangements show no little ingenuity on the part of the builders.

IN the Plattner or vat chlorination process the advantage lies in requiring no motive power. In the barrel process power is necessary, and this would make the latter process the more expensive if it were not for the largely increased capacity of the plant, due to saving of time. The ore is charged in a lead-lined barrel, together with chloride of lime and sulphuric acid and water. The barrel is closed and then revolved for several hours, when the charge is withdrawn, the liquor being drawn through a filter within the barrel. Sulphur dioxide is forced through the gold-bearing solution, followed by hydrogen sulphide, which precipitates the gold. In charging the barrel the water is first run in, and then the necessary amount of sulphuric acid. After this the roasted, pulverized ore is charged and on top of this the bleaching powder, which by this means is for a few minutes kept away from the acid which will decompose it, liberating the chlorine. The workmen are thus given an opportunity to close the barrel without inhaling the noxious fumes of the gas. If desired, the gold may be precipitated by the use of a solution of iron sulphate, but this requires so long a time that the sulphur dioxide and hydrogen sulphide are most generally employed. These latter may be employed in the vat process, as well as in the more modern barrel process. The only barrel chlorination plant ever installed in California was that at the Mayflower mine (now a part of the Fremont Con.), near Amador City. It was run only a short time.

THE measurement of broken quartz ore in a bin may be made on the basis of 20 cubic feet per ton. The capacity of ore bins, as usually stated, is based on the measurements of the bin, but the bin will not hold this amount unless level full, which it seldom or never is, unless the top be leveled off by shoveling. Thus, a bin of the usual form—that is, vertical front and sides, with back inclined at 35° and being 30 feet long, 14 feet deep and about 20 feet wide at the top—would actually contain, if level full, 4200 cubic feet of quartz, or 210 tons of ore; but, as the ore falling through the grizzlies and from the jaws of the breaker seldom fill the bin completely, the amount in the bin rarely exceeds 180 tons. The breaker should be set as near the front or vertical side as possible, as this will admit of filling the bin with ore to a greater height than if placed near the upper end of the sloping floor. If the floor be flat, a bin of the dimensions above given will hold, when level full, 420 tons, but there is no advantage in a flat bin, except storage capacity, and when the ore runs down through the chute door until the slope has reached the "angle of convenience," it will no longer run and shoveling must be resorted to at an expense of at least 15 cents per ton of ore. There is little, if any, advantage in having a narrow section of the bottom of the bin flat along the vertical side, for it only retards the free running of the ore when the supply gets low; and if shovellers have to be put into the bins, they work at a great disadvantage on the narrow flat surface, as they have not sufficient room for free movement, which is important in shoveling. The better plan is to put the breaker at the mine outside the mill and deliver the ore to the mill bins in cars entering the end of the building passing over the bins in the direction of their length. By this means ore can be distributed more evenly—coarse and fine—and the bins filled more completely than where the breaker is over the bin. Storage capacity should be provided outside the mill in bins built at the mine, and nothing but unfortunate topographical situation should induce a mill builder to put the breakers in the mill.

## Discovery and Development of the Homestake Mines of South Dakota.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS.

These thoroughly modern methods of ore handling are in strong contrast with the practice of early days, when the ore was hauled in wagons, often through mud up to the axles. Other changes from old-time methods are fully as radical as those above mentioned.

The somewhat primitive methods of milling the ore were improved from time to time. The raw copper plates, which for years had been depended upon to amalgamate the gold in the ores, were reinforced by the addition of silvered copper plates. In the earlier days the ore from the surface and superficial workings was remarkably free, and a high percentage of the values was saved in the battery and on the outside raw copper plates. A great deal of work was put on these plates, and a new plate was never considered in good condition to do successful amalgamation until it had been worked upon every day for at least a month. The plates were rubbed and scoured and given every care to put them in condition. As little gold as possible was removed, and the thought of employing a steel chisel in dressing plates or cleaning up was unheard of.

So free milling was the ore in those days that a check was kept on the run of ore by the simple expedient of crushing samples of two pounds weight, taken by the shift bosses in the various parts of the mine, and panning the pulp in a tub. The sampling room was equipped with two large cast-iron mortars. Over one was arranged a pestle suspended from a "spring pole." In this mortar the weighed sample was placed after drying on a large oven provided with a sheet of boiler plate for a top. The ore was broken down to the size of hazel nuts and transferred to the second mortar, over which was fixed an old machine drill mounted on a timber frame. In place of a drill, a stamp head, made by "upsetting" a bar of steel, was attached to the drill chuck. When the steam was turned on this improvised steam stamp quickly pulverized the ore fine enough to pass a 30-screen, in which condition it was panned in a tank situated at one side of the room. So familiar did the sampler become with this method of testing the ores that his judgment was surprisingly accurate, and he could forecast and regulate the bullion output by this method. In doing this, of course much depended upon the sampling as done in the mine, but the results showed that the sampling was representative of the existing conditions.

The silvered copper plates were added as previously stated. The new plates below the first old line of apron plates were made wider than the latter, to reduce the pulp flow to a thinner sheet. This worked so well that later a third row of plates was put in, which were given a still greater width, for the same purpose as before, and with equally gratifying results. As these two additional rows of plates had demonstrated their usefulness, but as the tailings still carried values, a fourth row was added and again the wisdom of this policy was made apparent by an increased saving. The upper row of plates was 4 feet wide—the original width of all the old plates. Each row added below was wider than the last, until the fourth row was reached, which was 6 feet wide. Mercury traps were early employed and were still in use, but although the saving of values was high and resulted in profit, as the mine workings increased in depth the percentage of sulphides in the ore increased, and the free-milling gold became proportionally less. The ore is all low grade, as compared with most other mines, running about \$4 per ton. The ore from the surface workings almost universally averaged better than this, but below the values decreased somewhat, until a normal condition was reached. In the lower levels of the mine the ore runs from \$3 to \$5 per ton. No oxidized ore of consequence is found below the 400-foot level of the Homestake mine and in most of the mines of the group it does not extend below the 200-foot level.

The increasing loss of gold in tailings came to be looked upon with much concern, and it was finally decided by T. J. Grier, the superintendent, to introduce the cyanide process in an experimental way, in an endeavor to ascertain what could be done to stop the heavy loss—about one-third of the value of the ore. C. W. Merrill was engaged to make these tests. The result was that to-day the Homestake Co. has two of the largest cyanide plants in the world—one located on Gold Run below Lead, treating all the ore from the mills at Lead, and another plant near the junction of Deadwood and Blacktail gulches, which treats the material from the mills at Terraville and on the north end of the property. These two plants have a combined capacity of treating over 2000 tons of tailings daily. Although the cyanide process has done much in improving the metallurgy of Homestake ores, it has been the result of long-continued and intelligently directed experiment, and the process is still in the development stage, for changes are not infrequently made in plant or

methods, and Mr. Merrill has been devoting much attention to the treatment of slimes with much success, and it is expected before these experiments are concluded that the tailings from the Homestake cyanide plants will be practically worthless.

One of the most important of the problems presented by the operation of mines on so large a scale was the development of sufficient water to make these extensive metallurgical operations possible. The watershed tributary to the Homestake mines, at Lead and at Terraville, does not cover over 2 square miles, and the amount of water available within that area is barely sufficient for a 20-stamp mill. At Central City, Deadwood gulch drains an area of approximately 12 square miles, but the amount of water flowing here is also inadequate, except in times of flood. In the early history of the property the need of water soon became apparent, and as previously stated, water was brought to Lead from several streams at the south ward, the most distant being nearly 20 miles away in a direct line. At one time it was seriously contemplated moving the mills to some of the larger streams on the prairie, north of the Black Hills, where a large and never-failing supply of water would be available, but it was decided to first further develop the water of the region south of the mines, which was done with only partially satisfactory results.

One of the most valuable water privileges in the northern Black Hills came into possession of the Homestake Co. when it bought the property of the Father De Smet Co. This company early secured a water right on Upper Spearfish creek, and in 1878 built miles of ditch, flume and pipe line, with the intention of conveying the water to Central City for use at the De Smet mill, and in this connection at least two long tunnels were driven through hard eruptive rocks about 10 miles west of Lead, near Carbonate. These tunnels are each about 1500 feet long and cost many thousands of dollars. The project was never completed by the De Smet Co., for the ditch and flume were abandoned after about \$400,000 had been expended upon them. Although the Homestake Co. was in control of this property as early as 1880, nothing was done with the Spearfish water right until about five years ago. The repeated enlargement of the several mills and the consequent demand for more water determined the Homestake management to develop and utilize the water of Spearfish creek. The installation was made, and now water is conveyed from Upper Spearfish to Lead. In this plant the water is carried 9 miles through a 28-inch vitrified pipe to a station equipped with both steam and electrical machinery. From this station the water is pumped to a reservoir 400 feet above the station, at the rate of 4500 gallons per minute. From this reservoir the water flows by gravity through 4 miles of vitrified pipe to the head of Whitewood creek. From this point the stream flows in the bed of the creek for 4 miles, when it is taken out and carried by flume to Lead. This plant cost about \$1,000,000, and is one of the most expensive hydraulic installations for private enterprise in the United States.

As illustrating the value placed on any available water supply in the early days, it is related of Samuel McMasters, the first superintendent of Homestake, and the man who laid the foundation upon which this huge enterprise rests, that he one day took a horseback ride up a neighboring gulch in the Bald mountain region about 4 miles from Lead. Here he saw two prospectors working in a tunnel from which poured a good-sized stream of water—a sluice head, as the miners called it. He reined up and inquired of one of the miners how he was getting on, and on being assured that the prospect looked fine asked permission to inspect it. Pleased at an opportunity to show their claim to a man representing such substantial interests, they gladly assented. After spending some time in the wet tunnel, ostensibly examining a small seam of ore, but in reality sizing up the flow of water and character of the ground from which it came, he returned to the outside and remarked: "I suppose you boys will sell this prospect. What will you take?" One of the partners suggested that \$10,000 was about right. "Too much for such a small prospect," said McMasters. "It may all peter out in a few feet. We would have to spend a lot of money to develop it, take all the risk and perhaps get nothing. Now I'll give you \$6000 for this tunnel—and \$60 a foot is pretty good pay for drifting in this ground."

The miners considered a minute and said: "Well, all right, she's yours for \$6000 cash."

"All right," replied McMasters. "Come down to the office any day and we will make out the deed and you can get your check." He then rode away up the gulch in a leisurely manner. On returning to Lead, he found the miners on hand with the deed made out ready for signatures and they for their check.

The following day several workmen might have been seen bulkheading the tunnel and others building a flume to convey the water to the Homestake mills at Lead. When the former owners of the prospect saw this they readily understood why the superintendent of the Homestake could condescend to examine a 100-foot tunnel and pay spot cash for it.

There are at the Homestake large compressors, some of them among the largest in the world. Compressed air is employed in drilling and in transporta-

tion both above and below ground. The air and water system are connected, so that in the event of fire underground, the air may be shut off and the water turned on. As the mine is over 1200 feet deep, the system is divided into sections, with 400-foot lifts. This is a wise provision and no great fire need be anticipated underground in these mines now, when this protection against fire and the mining methods now in vogue there are considered.

The mines do not make as great an amount of water as their extensive development would suggest. There is a large steam-driven pump on the 1100 level of the Golden Gate shaft which raises 550 gallons per minute, and a large Cornish pump at the 1100 level of the B. & M. shaft handles 400 gallons per minute. This water is also available for use about the mines.

The mining of such large amounts of ore requires tons of drill steel to be banded daily. Formerly all the drill sharpening and forging were done by hand, requiring the labor of a great many men. Now this work is done by three machine drill sharpeners—one on the surface, one at the 600 level and one at the 800 level, and as each machine turns out 600 drills every twenty-four hours, it will be readily understood how the placing of these machines in the mine, near where the drills are to be used, facilitates handling them. On the 600 level a large blacksmith shop has been fitted up for making repairs and doing general blacksmith work, and this also effects a large saving of time and money. Thus it will be observed that as the expense of mining naturally increased under the old-time methods, as the workings grew deeper, new and improved methods and machinery were introduced to offset the increasing disadvantages, until to-day mining on the Homestake is being carried on at less expense than during the years when conditions were, generally speaking, more favorable than they are at present.

A large amount of rock is still mined at the various properties of the group by the open cut and "glory-hole" methods. By the former the rock is blasted down onto the floor of the cut and is shoveled into cars run close up to the face, the larger blocks being "bulldozed," or "block holed." By the glory-hole or mill-hole method the rock broken down in blasting is drawn off through raises put up from some level below, and is drawn into cars from chutes built at the foot of the raises. This method of handling rock is the cheapest known in mining, and where it can be applied above an adit level, thus dispensing with hoisting, a very few cents per ton should cover the expense in large ore bodies and where the method is properly applied. At the Homestake the ore in the open cuts is shoveled into cars, which are made up into trains and hauled to the rock breakers, from which it drops into large bins. From these it is reloaded at a lower level and sent to the mills to be distributed whenever required.

Mining by the open cut system, as practiced at the Homestake, is now a pronounced feature everywhere of mining practice in large veins which outcrop at the surface. Up to this time all of the ore broken down upon the floor of the open cut is shoveled by hand into the cars. In some mines, particularly at the iron mines of Minnesota and Michigan and also in Wyoming, at the Sunrise iron mines, steam shovels are employed in this work, and this method seems adapted to the conditions in some of the cuts of the Homestake, but has not been introduced there as yet. In the early days some of the rich streaks were gouged out by leasers, who honeycombed their leases, leaving generally insufficient support. As a result the rather soft schistose ore bodies near the surface caved, and at one time many thousands of tons of ore were recovered by topping these caves from below and allowing the fine broken ore to run down to a level below and drawn into cars from a chute previously constructed at the foot of the raise. This ore was run down with little or no blasting, the working of the ground, due to subsidence and subsequent caving, having crushed and broken the most of it to a size which would easily pass the chute doors. It was occasionally necessary to put a man into the cut to work the rock down from the sides with pick and bar. He made himself safe by securing a rope around his waist, the upper end of the rope being attached to a drill driven in at the surface well back from the edge of the cut. Often the ore ran beneath his feet so rapidly that it was with difficulty he kept from being drawn down into the mill hole.

By the open cut system, when the rock is to be blasted, deep holes are drilled by means of the jumper or churn drill. These holes range from 12 to 20 feet in depth, are given a load of 10 to 15 feet from the face and are usually drilled in series—that is, several such holes are put down at one time. The holes are "sprung" repeatedly with nitro powder, and finally, when a chamber sufficiently large has been made by this process, black powder or low dynamite are charged together with 40% nitro powder and the holes fired. The result is variable, dependent on the character of the ore, but it usually dislodges 600 to 1000 tons, and often much more for that series of holes. The larger rocks are bulldozed, or black-holed, and the ore is then ready for the chutes or cars. The methods in open cuts with flat floors or in those provided with mill holes are essentially the same.

Chinese Methods of Mining Quicksilver.\*

NUMBER II—CONCLUDED.

Written by HENRY BRELICH.

The ore containing the "black" mineral is similarly crushed and treated direct for the metal, without any previous panning.

The circular retort furnaces in which the ore is treated are built in pairs 2 feet 6 inches diameter and 1 foot 6 inches high, and consist of an ordinary cooking pan, which serves as a receptacle for the ore, resting on a round fireplace built of unburned bricks, above which is placed an inverted pan having a hole in the center 12 inches in diameter. On the top of this is built a collar of clay 12 inches high, strengthened on the outside by a plaited network of bamboo, which extends a few inches above the clay collar and serves as a support for the topmost pan. The top of the collar is grooved in the center, and resting on its inner rim is another pan with a 12-inch diameter hole, covered by an earthenware pot, which, when the furnace is in operation, acts as a condenser. An annular space is thus formed between the groove, the lower part of the top pan, and the inner side of the bamboo network. The rim of the clay on which this pan rests is perforated with three holes, 3/4 inch diameter, known as the percentage holes, which are inclined towards the center of the furnace, and the amount of quicksilver collected within the annular space depends on the pitch of these holes, increasing as the angle is increased. The earthenware condenser resting on the top pan is luted with residues and the inside of the bamboo network is lined with clay.

About 50 pounds of ore is charged into the lower pan and heated with wood fuel, the quicksilver vapors condensing in the annular space and the earthenware pot, which is changed at intervals until the ore is exhausted, when the residues are withdrawn by means of a shovel with a blade at right angles to the handle, and replaced by another charge. The residues, especially in the case of rich ores, which still contain imperfectly burned ore, are ground, sluiced and the concentrate again retorted. While the condenser is being changed the ore in the pan is stirred with a wooden pole, and copious fumes escape through the opening. During the operation the condenser becomes coated with numerous minute globules of quicksilver, which, after its removal, are run together by rubbing the surface with a rag, and form in a pool at the bottom of the pot. The losses, as far as can be estimated, vary between 30% and 40% of the total quicksilver.

When treating rich ores, about 1 catty (1 1/2 pound) of quicksilver is collected in each cleanup from one of the earthenware condensers. The metal is poured into bamboo flasks and transported to the river port in pigs' bladders.

The following data regarding the working of these furnaces were obtained from a native smelter treating tailings, where four furnaces (eight retorts) are in constant operation:

Number of men employed per twenty-four hours = three. (The men work at the furnace only twenty-four hours every four or five days to avoid becoming salivated.)

Wages per twenty-four hours = 1200 cash—say 1s per man, or a total of 3s.

Total average amount of ore treated per twenty-four hours = 3000 catties (4000 pounds).

Each furnace is charged per twenty-four hours = seven to eight times.

Average yield, including final recovery when furnace is pulled down, per twenty-four hours = 8 catties (10.7 pounds).

Cost of fuel per twenty-four hours = 3200 cash (about 8s 6d).

The cost of one furnace (two retorts) complete is 4000 cash—say 10s 9d—lasting about one month, during which time it is constantly undergoing repairs.

In addition to the furnaces at work near the mines, a considerable number are owned by individuals who carry on custom smelting, receiving in payment the quicksilver collected in the annular space through the percentage holes. The ore treated in these furnaces is obtained either from the mines or from the dumps, and frequently by theft.

These custom furnaces, producing singly a comparatively insignificant amount of quicksilver, are nevertheless important factors in the production of the metal, as a large percentage of the total output is derived from these numerous sources.

The owners of private mines have a set of furnaces for rich ore, and one for poor ore, and, if the miner strikes a rich pocket, the ore is treated in the "rich ore" furnace, whose "percentage holes" are so inclined that the furnace owner receives about 40% of the total distillate as his share. This is an established custom to which the miners willingly conform.

STORES AND SUPPLIES.—All the necessary stores and supplies required by the miners in connection with their work are produced and manufactured in

the province, with the exception of wick, which is imported from the province of Szechuan.

The following is the cost of the principal articles which may be procured locally:

Wrought iron, per pound.....	s.	d.
Steel, per pound.....	0	1.4
Sulphur, per pound.....	0	2.1
Niter, per pound.....	0	1.7
Charcoal, per 100 pounds.....	0	10.2
Oil, per pound.....	0	1.6
Wick, per pound.....	0	6.8
Firewood, per cord (5 feet by 5 feet by 5 feet).....	8	6.4
Ore baskets, each.....	0	1.4
Wrought iron lamps, each.....	0	3.8
Cast iron pans (used throughout China for cooking purposes), each.....	2	8.0
Wooden pans, each.....	1	7.0

MINING LAWS AND TAXES.—Mining laws are practically unknown, and although of recent years mining regulations have been issued by the imperial government, they have not been enforced, and the natives are ignorant of their existence. The Government owns no land in the neighborhood of Wan Shan Chang, which is the "ancestral" property of two or three families and their numerous progenies.

A Chinese land owner possesses all surface and mining rights within his boundary, consequently any mining carried on in his property entitles him to the receipt of a small tax, which is paid either in cash or kind by the miner. In addition to this tax there are numerous other arbitrary taxes or "squeezes" levied by the officials under whose jurisdiction the mines are situated.

The product of the mines is indirectly taxed through the "ching fu," or weighers, who are the principal merchants of Wan Shan Chang, to whom, on payment of a monthly tax to the prefect, is given the sole right of purchasing all the quicksilver and cinnabar produced, with the exception of that which is produced from those mines where the owner pays a tax direct to the officials, and is thus exempted from selling the product to the weighers.

The price paid by the weighers is somewhat lower than the prevailing market price, usually about 100 cash (3.2d) less per catty, but this deduction is either increased or decreased according to the demands of the market.

The term "squeeze" should logically be confined to the illegal detention or extortion of money. Thus, an official has a right to levy a certain tax in granting rights to work a mine or open a shop, but such rights are most likely to be granted to one who will pay an additional 20% or 30% as a bribe. The legal and just tax levied by an official is, however, commonly called a "squeeze." The author estimates that, notwithstanding all taxes and squeezes, the output of a mine worked by the natives is taxed only to the extent of about 2% on the net value.

WEIGHTS, MEASURES AND CURRENCY.—There is no standard for the weights and measures in use, and there is considerable variation throughout the province.

The catty (1 1/2 pound) is the representative weight, and may be regarded as being fairly uniform throughout China, whereas the picul "dahn," which should be equal to 100 catties, is not a fixed quantity, and when mentioned in a transaction it is always advisable to inquire "of how many catties?"

Quicksilver in quantities above 5 catties is sold by measure and not by weight. The measure used is made of brass and shaped like a truncated cone, 5 inches high, 3 inches diameter at the base, and 1 1/2 inch diameter at the top, and holds when full 5 catties.

The foot "ch'e" is the measure used by the miner, and is equal to about 15 inches, divided into 10 "ch'en," and this again divided into tenths, "fun." Measurements equal to or exceeding 10 "ch'e" are referred to as so many "chang," one chang being equal to 10 feet.

The only coin in circulation is the cash "chien," a circular disc differing in size\*\* and weight, made of copper or brass, with a square hole in the center, through which it is threaded on a string up to 1000 nominally, but actually containing 960 to 980 cash (2s 7d) and weighing 6.2 pounds. Silver ingots, called "uen hao,"† of varying weight and fineness, are also in use, and they are exchanged for cash at a certain rate per ounce ("leeang"‡) of silver, which is dependent upon the fineness of the silver, the quantity and size of the cash, and upon the cash reserve in the hands of the merchant bankers.

Notes of 1000 cash, face value, issued by the bankers are also locally in circulation.

As regards currency, the rate of exchange constantly varies. There is no such coin as the tael, which is merely a name for an ounce of silver. The term is only used in the treaty ports, and is unknown in the interior, where the value of an article is always stated as being equal to so many ounces or "leeang" of silver, which varies in every town. The exchange for an ounce of silver is also variable, and is now, roughly speaking, 1000 cash = one Kweiyang tael, but the author has known it as high as 1400 cash.

For the purpose of this paper the following rate of exchange has been taken:

- 1 Shanghai tael = 2s 6d.
- 1 = 8 Shanghai taels
- 1 Kweiyang tael = 2s 8d.

\*\*"Dien chien," good cash, about 1 inch in diameter. "Mao chien," bad cash, about 3/4 inch in diameter.  
† Called "sycee" at the treaty ports.  
‡ Called "tael" at the treaty ports.

1 Kweiyang tael = 1000 cash.  
1 Kweiyang tael = 1.166 ounce troy of silver.  
1 Kweiyang tael = 1.065 Shanghai tael.  
1d = 31.2 cash.

The Kweiyang tael has been taken in this paper because it represents the tael as used in the provincial capital of Kweiyang.

PRODUCTION.—There are no data available concerning the former output of these mines, hence no attempt at any estimate can possibly be made. It is stated that thirty years ago the output amounted to 7000 catties (9300 pounds) of cinnabar and 3000 catties (4000 pounds) of quicksilver per month, and to have been maintained at these rates for a number of years, when the production of quicksilver increased, while the output of cinnabar diminished.

During the last few years the output has averaged 3000 catties (4000 pounds) of quicksilver per month, while the cinnabar output has been constantly decreasing, and now averages about 200 catties (270 pounds) per month from native sources only.

The metal is exported from Toon-Yen, either in pigs' bladders or iron flasks, to other parts of China, where it is used for the manufacture of vermilion, for which there is a great demand throughout the Chinese empire.

In the following table the price of quicksilver at the mines is compared with the London quotations at the corresponding period per flask of 75 pounds:

Year.	London Av. Price per Flask of 75 Lbs.	Mines Av. Price per Flask of 75 Lbs.
	£ s. d.	£ s. d.
1901.....	9 2 6	6 2 11
1902.....	8 15 0	7 19 3
1903.....	8 12 6	7 17 11
1904—January to July.....	8 0 0	7 1 7

The large cinnabar crystals detached from the ore, and the "red" cinnabar extracted by panning previous to the ore being treated for the metal, find a ready sale in the local markets. It is usually sold in packets of 100 ounces (8.3 pounds), containing varying proportions of fine and coarse cinnabar, at prices ranging from 850 cash to 1300 cash (2s 3.2d to 3s 8.6d) per catty (1 1/2 pound), while the larger crystals, which are now much rarer, are often sold without any admixture of fine cinnabar up to 5000 cash (13s 1.2d) per catty.

CONCLUSIONS.—From the meager information one is able to gather regarding this industry, there is no doubt that the mineral was at one time mined on a very large scale, and that the industry was in a far more flourishing condition, and the output of the metal and cinnabar much greater than it is at present. The extensive underground excavations, which stand as monuments of previous mining activity at the principal localities where the mineral occurs, form conclusive evidence of the work which has been accomplished in former times.

Apart, however, from other quicksilver deposits which may be revealed by further systematic prospecting of the large portion of this province which is as yet unexplored, the condition of those mines now in operation by the natives is such as to warrant the expectation that a constant output will be maintained for many years to come.

Gold and Iron in Black Sands.

Written for the MINING AND SCIENTIFIC PRESS by ALGERNON DEL MAR.

For those interested in the treatment of magnetic sands for both the gold and iron contents a few preliminary experiments may be of interest. I greatly regret that the iron experiments were not accurately recorded and were not followed up on a scale sufficiently extensive to make commercial factors available. I was more interested in the gold extraction, and when I found that the sands would not average up to expectation, the preliminary experiments here recorded were not followed up. As to the gold contents, contrary to the opinion of a writer in this journal (that magnetic sand was not readily amenable to cyanide treatment on a laboratory scale), I had no difficulty in reducing the value from \$3 to a trace. The gold was in the form of fine specks, which could be separated from the magnetic sand by careful panning. This extraction would give a handsome profit on \$3 sand, but the trouble was to find extensive deposits carrying this value.

The sand contained about 60% magnetic iron. To concentrate to a nearly pure magnetic product need present no difficulties with magnetic separators or on concentrators. For my purpose I simply washed off the sand and with the aid of a magnet obtained a nearly pure iron ore. Now the difficulty comes. First, this must be smelted with oil as fuel, and to do this it must be in a form whereby the smelting operation would be practicable. Sand alone with an oil blast is out of the question. A furnace with an inclined bed had already been patented, for smelting copper ores I believe, but this did not appeal to me as practicable for iron ore, so, after many experiments, I at last hit upon the idea of mixing the magnetic sand to a thick paste with crude oil, shaping the "mud pies" into small bricks and, by baking over a wood fire, getting rid of all the volatile oils, leaving the magnetic sand in the form of a hard bri-

quet combined with the fixed carbon and impurities of the oil. Thus far I had succeeded in making briquets containing a certain per cent of carbon, which amount, I regret to say, was not determined. To satisfy myself that iron could be reduced from this briquet, I mixed small pieces with a little coke and, using two crucibles (one inside the other, with charcoal between) and with a bellows I succeeded in obtaining a small quantity of reduced iron. This experiment I consider of value, in so far as it may point the way to future experimenting.

I would recommend the following procedure: Concentrate the sand to a pure magnetic product. Briquet the sand with crude oil, using the gases given off as fuel in the briquetting operation, for power in running blowing engines and for a gas blast independent of the air blast. I have no doubt the successful smelting of magnetic sands can be accomplished along these lines, and I hope others, who have more time and leisure, will work out the scientific and commercial data.

The above process, as suggested by Mr. Del Mar, does not differ essentially in principle from the Eames or Carbon Iron Company's process, wherein iron ores (hematite) were pulverized in Chile mills and this pulp mixed with coke which had been dipped in clay water, dried and pulverized. The charge was not briquetted, but spread on the hearth of a reverberatory furnace and reduced in a reverberatory furnace, natural gas being the fuel employed. The glowing surface of the charge, when fused, was rolled up into balls by means of hand rables, and these placed in a "squeezer" and pressed into "blooms." It made a superior grade of carbon iron, and found ready sale in Pennsylvania, where it was made. That gold associated with black sands can sometimes be cyanided is undoubtedly true, but as the gold so occurring is not always in the same physical condition the results naturally vary greatly. If the gold be comparatively coarse, the cyanide solution works too slowly for satisfactory commercial results. If the gold is chemically combined or mechanically inclosed in the particles of sand, this gold will yield but slowly, if at all, to the dissolving influence of the cyanide.—Ed.

### Exhaust Steam in Mine Workings.

In many of the small collieries in New Zealand steam pumps—generally of the direct acting "Duplex" type—are used, and are not as a rule of very great capacity, says the Minister of Mines. Steam is conveyed to the pump underground from a boiler at the surface, but the exhaust steam often presents a difficulty. If allowed to escape freely into the workings it is very liable to set up conditions inimical to the stability of the roof, besides making everything hot and wet for a considerable area, and therefore the rough-and-ready expedient of allowing the exhaust steam to discharge into the sump water is frequently adopted. This certainly reduces the nuisance, but at the expense of efficiency, owing to the extra back pressure on the pistons caused by the head of water over the discharge end of the exhaust pipe.

A very simple method of meeting the difficulty (which not only gets rid of the undesirable conditions entirely, but actually assists the pump owing to the condensation of exhaust steam and the vacuum obtained) has, on my recommendation, been recently carried out at two small mines with satisfaction to the management. The arrangement is as follows: The suction pipes are laid as usual from the pump into the water-lodge or sump, but the lowest length of pipe is somewhat larger than the pipes above.

The exhaust-steam pipe is carried down alongside the suction pipe and turned into it at the lower end as shown in the sketch. Near the pump a plug tap or cock is placed on the exhaust pipe, but between this tap and the pump a short branch pipe (of the same diameter as the exhaust pipe) must be connected and fitted with a similar tap. These two taps should be connected to one lever so that the operation of opening one closes the other. Before starting the pump to work, the tap on the main exhaust pipe must be closed, and that on the branch pipe opened. On the pump being started this allows the exhaust to discharge into the surrounding at-

mosphere, but it is desirable to continue the branch pipe a few feet past the tap and lead the exhaust into a small tank of water. (In the case of small pumps an oil drum is ample.) When it is ascertained that the pump has got fairly to work on the water, the lever connecting the taps is pushed gently over, and the exhaust steam then passes down the main pipe and into the suction. It is to be remembered that the taps must be reversed by the connecting lever a few seconds before the steam is shut off from the pump to avoid flooding the cylinders, and also that where leather pump buckets are used care should be taken not to let the pump get on air before altering the direction of the exhaust steam, otherwise the heat will damage the leathers.

Actual experiments have demonstrated that an increase of 121% in the working speed and capacity has been attained by the use of this simple condenser. The method has its limits, but is eminently suited to pumps designed for comparatively low heads.

### The Rational Design of Head Frames.

TO THE EDITOR:—With reference to the comment that Mr. Chodzko makes on my notes on head frame design, I venture to call attention to the fact that my former article on this subject was published before the publication of his design for head frame on the Mother Lode, and that a drawing is now in my possession dated March, 1899, which is substantially the same as the diagram accompanying my last notes.

I am far from making the claim that no head frames have been designed having the back columns in the plane of the resultant working stress, but, on the contrary, I have no personal knowledge of this principle having been consistently applied in such a manner as to take full advantage of the possible economies of material inherent in this design, as presented recently, and in Mr. Chodzko's head frame I note that the dimensions of the steel employed in the front columns is apparently the same as in the back, where the heavy working strains occur, and a concentration of material would naturally be expected.

In conclusion, I would call attention to the fact that in my design the weight of the sheaves and the working strains are taken by the ends of the compression members direct, eliminating all eccentricity of strains. This arrangement is absolutely necessary for mathematical consistency, and I am more interested in its value than in its origin, although, so far as I know, the design shown as a whole is original, and dates from the early part of 1899. The following from my former article on this subject makes the principle involved so plain that anyone could have made up such a design without difficulty:

But in cases where the cost of material, erection and freight is so great as to call for the best possible use of material and labor, it would be possible to design a frame that, although not more rigid than the form above discussed, would be equally so, and would not require more than about 60% of the amount of material. In this form the main strength would be concentrated in a panel set in, or a little back of, the plane of the mean resultant of the strains due to the tension on the ropes. No matter how suddenly this strain is applied, the resultant is always the same, and the strain on the panel could only be compressive, having no tendency to pull it back or throw it forward. This being the case, the rest of the structure could be designed with only sufficient strength and rigidity to carry the weight of the main compression member, which, owing to its inclined position, would tend to fall toward the shaft.

The part of the structure in front of the main compression member would be merely a light framework, with its main members designed to resist tension rather than compression, and would carry the guide posts and part of the platform surrounding the sheaves. It would be well anchored to a heavy foundation, so that in case of overwinding (when the resultant, owing to the fact that the cages would foul the sheaves, would fall outside the axis of the main member, and would coincide with the center of the rope), the vertical members of the light bracing would be able to resist the tensile strain that would result and prevent overturning the structure, the strain possible being proportionate to the strength of the rope, the base in side elevation to the structure, and the distance from the base of the main member to the center of the rope, at right angles to the rope.

This last distance would always be somewhat greater than the base of the structure in side elevation, owing to the fact that the vertical members of the front bracing would be set back of the shaft, but the difference would not be so great and the limit of tension that could come on these members through the fouling of the cages would be practically the strength of the rope, and it is plain that if the section is sufficient to sustain the weight of the main compression members, it would be amply strong in tension to break the rope.

In the end elevation of this type of frame the main compression members would be brought as near together at the top as possible, and well spread at the base for lateral stability, but the front bracing could be vertical and consist of three main members tied to the compression panel with light braces, firmly connected at the top and well anchored at the base to a heavy foundation.

Although this design is, in the opinion of the writer, perfectly practical and based on correct mathematical principles, it is so revolutionary and defiant of all tradition that it is doubtful if most mine managers would have the courage to construct one on these lines, and so long as the form that has been adopted for the Nevadaw and High Ore mines is not considered too expen-

sive, there would be no particular object in using this, but where the question of freight and material is of the first importance this design certainly offers a method of obtaining the greatest results for the amount of material employed, and by the introduction of iron tension rods in the vertical members of the front bracing the design is as well applicable to a wooden frame as to steel, and the economy of material equally striking.

GEO. S. BINCKLEY.

### Park City Mining District, Utah.\*

Written by J. M. BOUTWELL.

Since the publication of the last statement on this district, in Bulletin No. 225 of the United States Geological Survey, the extensive exploration there described, which had then been persistently carried on for more than a year without adequate results, has at last been rewarded by valuable discoveries. The object of this sketch is to give an account of the general results of this successful prospecting and of the principal recent mining developments. In the earlier statement it was pointed out that as a result of the extensive exploration "some slightly mineralized ground has been opened, a small amount of ore has been discovered, and in the ground which was more wisely located the indications are good." During the last year these indications have materialized, and, although nothing comparable with the Quincy strike is yet announced, new ore bodies have been found, and three of the new properties have begun shipments.

At the Kearns-Keith mine extensive beds of sulphide ore with some carbonate have been discovered in the foot of the main vein. In the course of cleaning out old workings and connecting the mines forming the present consolidation, including Crescent, Apex, and Hanauer workings, considerable ore has been taken out and the main vein has been opened in new ground—notably to the southwest. The new concentration mill, a copy of one unit of the Silver King mill, has been in daily operation on the ores from this property and makes regular shipments.

In American Flag ground a strong ore-bearing fissure has been opened to a depth of more than 1000 feet, and at a number of levels for several hundred feet along its strike. Although no attempt at stopping for regular shipments has yet been made, several carloads of ore taken out in the course of development have been shipped. These yielded excellent returns, indicating that the ore carries good values in silver, gold and lead, and some copper.

In the New York one result of considerable exploration has been the discovery on the 400-foot level of a fissure, which, on being opened down to the 600-foot level and below, has yielded several shipments of high-grade silver-lead ore with accessory gold. In the Naildriver prospecting has ceased and a reduced force has been taking out ore struck several years ago. The Scottish Chief has made additional shipments of rich ore and continued active exploration. Some ore has been extracted from the Comstock and California, which was treated in the mills at those properties. The old Glencoe property has been reopened and the mill and mine are being put into shape for regular work. In some of the other smaller properties, in which work has been begun in only comparatively recent times, development is still actively in progress. After encountering unusual difficulties from water, the management of the West Quincy property has effected an agreement whereby its ground will be opened and worked at a depth through the Little Bell.

In some of the great properties encouraging results have also attended prospecting. In the Daly West, a strong ore-bearing fissure, the back vein, which has afforded considerable ore in the adjoining Daly-Judge property, has been found, and its ore is being actively stoped. The great Daly-Daly West vein, the main single fissure of this property, has been opened to the 1550-foot level and found to carry a large body of milling ore. Arrangements have been perfected with the Ontario and Daly companies for extending the 1500-foot level Ontario and 1700-foot Daly into the Daly West and prospecting its ground at this depth (2100, Daly West). With a view to treating the increasing amount of milling ore yielded by this mine, the capacity of its concentrating mill has been considerably enlarged and a tailings plant erected and equipped with the Sherman classifiers and slime-settling tanks, Wilfley tables (ordinary), and Wilfley slime tables.

In the Daly-Judge, exploration of virgin ground at a depth on the west has already resulted in cutting some very high-grade ore. As a result of prospecting in promising ground of the Daly, through the Mazepa shaft, those upper workings have been closed and the old Federal tunnel is being driven ahead to prove this ground at a depth. The other properties, large and small, have maintained their regular operations.

These newly discovered ore bodies, with a single exception, occur as veins in northeast-southwest fissures. The exception is the replacement ore in the Kearns-Keith, which lies in beds in the foot wall of

\*See illustrations front page.

the main fissure and takes the place of portions of limestone strata. In the Silver King and Daly West mines no new bodies of high-grade "bedded" ore have been recently found comparable to those which afforded the large shipments of crude ore. Considerable areas of the ore-bearing limestones remain unexplored, however, in each of these mines, and they are now being extensively and thoroughly prospected. The boom in 1902 resulted in an unprecedented number of new locations, the incorporation of several large companies, and a vast amount of prospecting. During 1903 the mining industry gradually resumed its normal condition, and newly formed companies settled down to persistent, serious development work. The last year, 1904, has witnessed the successful outcome of this extensive exploration in the discovery of ore and the addition of three shipping properties. This tends in a measure to offset a decrease in the annual output from the camp. Furthermore, the discovery of new ore bodies in large mines, promising developments in other properties, amicable arrangements between neighboring companies for prospecting through adjoining ground, and various surface improvements mark important progress in the mining industry in this district during 1904.

## THE PROSPECTOR.

The rock samples from Descanso, San Diego county, Cal., are typical norite, a basic igneous rock, in which large crystals of feldspar and hornblende form a prominent characteristic feature, giving to the rock mass a spotted appearance due to reflection of light from the cleavage planes of these crystals, but which spots on the rock disappear upon changing the position, and a new set making its appearance. Similar rocks occurring in the Lake Superior region have been called by J. D. Irving lustre-mottled rocks.

The rock specimens from Table Rock, Cal., are determined as follows: No. 1 is a typical syenite, consisting of orthoclase, feldspar and hornblende. No. 2 is probably diabase, judging from its structure, but the rock is too much decomposed to make its identification positive; it contains pyrite. No. 3 is amphibolite schist (talc schist), carrying a large percentage of pyrite (iron sulphide). No. 4 is an altered rock, probably granite or grano-diorite, much silicified and carrying pyrite; it is essentially an ore and may contain gold and silver. No. 5 is a metamorphic rock in which there is a development of considerable garnet, with little veins of iron oxide and quartz. No. 6 is a much decomposed rock, probably diorite or granite. The feldspars are wholly kaolinized and quartz is not abundant. The rock contains bunches of iron sulphide, and may contain gold and silver.

The rock samples from San Rafael, Cal., are: No. 1, glaucophane schist. The blue mineral is the variety of hornblende known as glaucophane. No. 2 is red jasper. It contains no cinnabar. The red color is due to microscopic particles of red iron oxide.

The rock samples from Golden, N. M., are metamorphic, probably on a granite contact. The rocks contain a granular mixture of quartz and feldspar, with abundant garnets and calcite. The bright scaly metallic mineral is specular iron (a variety of hematite). There is also much epidote (green mineral), and magnetite in black grains scattered through this interesting rock. The most prominent constituent is the brown garnets.

The sample of black sand from Ketchikan, Alaska, consists principally of iron ore in the form of rounded grains, of which about 25% is magnetic, the balance being non-magnetic and is probably titanite iron. The lighter colored grains are quartz, epidote and other hard minerals. No gold can be seen with the aid of a powerful loupe, an unusual thing in auriferous beach sands. Still, the gold may be present. An assay would determine this. If the gold is not free, it is doubtful if it can be saved by amalgamation or cyaniding, but concentration might increase its value somewhat, whether the gold is associated with the iron grains or with the quartz grains. The elimination of either would raise the value of the remaining material. Some experiments should be made with this sand.

The rocks from Randsburg, Cal., are: No. 1, diorite. The rock contains a small amount of pyrite. No. 2 is considerably altered, but is apparently diabase. No. 3 is a semi-schistose diorite and has been silicified and otherwise metamorphosed.

It is difficult, if not impossible, for the prospector to distinguish the various types of greenstone, one from another, in the field. Diorites and diabases look much alike, and the general field term greenstone is sufficiently close and answers every purpose. Moreover, it is understood by geologists generally that when the term "greenstone" is employed, a doubt as to the exact classification of the rock is expressed. Porphyry is an equally convenient name

for many acid eruptives, and is so understood by most geologists, though some restrict the application of the name to those rocks having porphyritic crystals.

## Boiler Waters and Their Treatment.\*

NO. II—CONCLUDED.

Written by W. M. BOOTH.

In answer to letters sent to several of the largest firms of the United States, I have received the following: (The names are withheld, as it was assumed that this was a confidential matter).

1. "We have your letter of January 28 asking for our opinion as to the best material for use in softening water.

"The principal trouble with the water in this neighborhood is that it contains free sulphuric acid, together with the sulphates of lime and magnesia. In order to counteract the effects of these salts, we have been introducing sodium carbonate directly into the feed water. This treatment, of course, does not prevent the formation of a scale in the tubes and we find it necessary to use a mechanical cleaner at least once in four weeks.

"It is our opinion that the feed water should be treated and the scale-forming solids removed before the water is pumped into the boilers, and it is our intention to provide an arrangement of this kind in the near future.

"Owing to the cost of most of the chemicals which will soften water, such as we have here, we believe that the most satisfactory materials are sodium carbonate and lime."

2. "Referring to your inquiry of the 28th inst., regarding water softening for steam boilers, we beg to say that we have used several of the special compounds in the market for this purpose and several compounds act effectually in the absence of a regular purifying plant.

"We use at several of our works the regular lime and soda process, which are the essential elements in the principal water-softening plants, the difference between the apparatus being one principally of detail of operation. When the proportions of lime and soda are properly regulated to suit the particular water used and care taken that neither of the chemicals be used in excess, it is probable that the best results now known can be thus obtained."

3. "Yours of the 25th received.

"We use nothing to soften our water before it reaches the boilers. We use a boiler compound and find that there are several in the market, any one of which is good. These compounds are composed mostly of soda ash and tanning matter. We have also found that when the boilers are idle, a solution of soda ash put in and allowed to stand several days softens the water and prevents scaling."

4. "We are in receipt of your letter of January 28th, asking an opinion in regard to the best material for use in softening water for use in boilers. It is impossible to give an opinion without the knowledge of each individual water to be softened.

"Of course you know that soda ash, tri-sodium phosphate and lime are all of value, when used with the proper waters. Zinc and coal oil have in certain cases been found successful."

5. "Your favor of January 25th was duly received here and we beg pardon for not having replied before this time. However, we hardly know what to say to you in regard to boiler compounds and our experience, in taking care of our boilers, to keep them free from scale, as it has been a study with us for years and we have never been able to find anything that is perfectly satisfactory.

"In some of our boilers we use condensed water, from the steam-heating coils, also the water from the roofs, but that is confined to the shell boilers. In these we use tri-sodium phosphate, putting it directly into the boilers, also using the proper tools to clean the boilers with, and in this way we have got along very well, but our water-tube boilers constitute another problem.

"We have never been able to use tri-sodium phosphate in the water-tube boilers, as it would make the water foam. What we use in connection with these is a filter, and while we do not obtain perfectly satisfactory results, it works better than any other plan we have tried. The filter plant is charged with caustic soda and quick lime. We could not state the exact proportions, but it is governed by the tests of the water as it goes to the boiler; these the writer does not exactly understand. But in this way we arrange to keep our boilers in a very satisfactory condition.

"The water we use varies somewhat in scale-producing properties, as it is much higher at certain times during the year, containing more lime. So there is no rule we can establish to keep the boilers in perfect condition. We have to scrape the tubes occasionally and go over them once in about three weeks. We would be very glad to find some means of purifying the water perfectly, but this is no doubt impossible."

6. "Referring to your favor of January 28th, in which you request that we give you our opinion in reference to material for use in softening water in

\* The Chemical Engineer.

boilers, and also before the water reaches the boiler, we would say that as far as our plants are concerned, it is not necessary for us to use any water-softening apparatus, for the water is sufficiently soft for our purpose and does not necessitate any further softening.

"We have at times used kerosene oil to prevent the scaling, and the same has been of some service. We have also found that a water-feed heater can be used to advantage for purifying the water, cleaning this heater out very frequently.

"Owing to the fact that hard water has not been one of our problems, we have never made a study of the subject, and for that reason we can hardly give you our opinion. By getting into communication with the manufacturers of any water-softening apparatus, you could doubtless obtain much information that would be of service."

7. "Replying to yours of the 18th concerning water purification. As the material used for softening water, either in tanks or in boilers, varies with the water found in different localities, it is desirable to make a chemical analysis of the water it is desired to soften, before applying the remedy, and as this varies so much in different localities I would suggest that you take the matter up with railroad companies in different part of this country.

"The Chicago & Northwestern, Southern Pacific, Rock Island, Santa Fe and a number of other roads have gone into this question quite extensively. You will also find a large amount of information in the railroad papers. I think there was quite a complete report published by Mr. Davidson, chemist and engineer of tests of the C. & N. W. Ry. in the proceedings of the Western Railway Club some time ago."

8. "In answer to your specific questions, I can only say that it appears to be impossible to give any general rule for the proper treatment of boiler waters. Some of them need no treatment at all, and others are so bad that it hardly appears practicable to render them fit for use by any treatment at all. Our own practice is to analyze troublesome waters before giving an opinion concerning them. The treatment recommended is then based on the analysis. It often happens, of course, that the nature and amount of the dissolved solids are already known by a previous analysis by some other chemist, as, for example, when the water is drawn from a city supply. In such cases we do not have to make a new analysis. Unless the character of the water is known to have materially changed since the first one was made; but in every case, as I have said, it is our intention to know just what the particular cause of the trouble is, before suggesting any specific treatment.

"Soda ash is undoubtedly the commonest substance in use for the prevention of scale or corrosion."

In concluding this paper it is difficult to sum up the most important factors in connection with the purification of boiler waters. A great variety of mechanical and chemical appliances has appeared. It is pretty generally conceded that pure distilled or rain water cannot be used for boiler purposes, and where its use is compulsory, it is the custom to lime the water slightly. The active form of air and other dissolved gases found in rain water is capable of causing severe corrosion at the ordinary temperature; without the aid of incrusting solids of any kind. The problem becomes very complex when we add heat, pressure and chemical salts. It is under these circumstances that we have to resort to settling tanks, feed-water heaters, coagulants, boiler compounds and water-softening plants, and each finds its place in the special treatment required for a special water.

## The Mint and the Miner.

The United States Mint comes into frequent and direct contact with many producers of gold and silver, but there are many more whose knowledge of mint regulations and charges is either uncertain or erroneous. For the benefit of the latter class the following is printed:

Revised table of charges at the mints and assay offices of the United States, as fixed by the Director of the Mint, and approved by the Secretary of the Treasury, January 2, 1900:

1. MELTING CHARGE.—A charge of \$1 shall be imposed for each melt of bullion, except in the case of uncurrent United States coin and fine mint bars.

2. PARTING AND REFINING BULLION (rate per ounce gross).—On silver bullion containing less than 300 thousandths of gold, three-fourths of 1 cent per ounce. On bullion containing from 300 to 500 thousandths of gold, 2 cents per ounce. On bullion containing over 500 thousandths of gold, 4 cents per ounce. Silver allowed the depositor shall be calculated on the basis of refining the gold to 990 thousandths. When bullion contains less than three-tenths of a thousandth of gold it shall not be reported for the benefit of the depositor. Base bullion containing less than 300 parts of gold per thousand shall pay a charge of 2 or 3 cents per ounce, or such material may be declined, at the discretion of the chief officer. If the alloy be all good copper when but one of the precious metals is present, the charge may be one-half cent per ounce.

3. REFINING SILVER (rate per ounce gross).—A refining charge of three-tenths of a cent per ounce shall be imposed upon silver bullion free from gold, assaying from 998 to 999½, and a charge of four-tenths of a cent upon such bullion assaying from 980 to 997½. Bullion

below 980 shall be subjected to the parting or refining charge of three-fourths of a cent per ounce.

4. TOUGHENING CHARGE.—

Gold bullion ..... 1/4 to 2 cents per ounce gross.  
Silver bullion ..... 1/4 to 1/2 cent per ounce gross.

This charge is made to cover the cost of fitting brittle fine bars for coinage operations and shall not be imposed upon unparted bars except in special cases where it is necessary to toughen an unparted bar returned to the depositor; or, when the bullion contains iridosmine, etc.

5. COPPER ALLOY.—Two cents per ounce of copper required.

6. BAR CHARGE.—On bullion deposited for fine bars not required to be parted or refined, and for standard or unparted bars:

Bars of fine gold per \$100 value ..... \$0.04  
Bars of fine silver per ounce ..... .001  
Bars of standard gold per \$100 value ..... .10  
Bars of standard silver per ounce gross ..... .001  
Bars of unparted bullion per ounce gross ..... .001  
Small gold bars (less than \$5000) ..... .05 per \$100.  
Small silver bars (less than 125 ounces) ..... .001 per ounce.

The following rules for the guidance of depositors in making shipments of gold bullion to the United States Mint, San Francisco, Cal., have been made by Frank A. Leach, superintendent:

No. 1. No shipment of less than three troy ounces will be received.

No. 2. All express and other charges must be prepaid.

No. 3. Each shipment must be securely packed and sealed.

No. 4. Address the shipment to "Superintendent, U. S. Mint, San Francisco, Cal.," giving name and address of consignor.

No. 5. Forward a letter by mail notifying the mint of the shipment, giving its approximate value, and, if convenient, the number of ounces, troy weight; also directions as to the disposition of the proceeds. We must have specific instructions from the consignor in regard to the returns, as we cannot file the shipping tag nor assume any authority therefrom.

All remittances of money, checks, drafts or money orders from the mint in payment to depositors are sent at their risk. The Government assumes no responsibility after the money leaves the mint, it being forwarded simply as an accommodation.

Something More About Head Frames.

The elementary principles which underlie head-frame construction are well understood by engineers who have been brought into contact with this branch of mechanics. Under ideal conditions the engineer can build ideal structures; but often topographical considerations and the requirements of the particular mine where a frame is required make ideal construction difficult. In some instances the hoisting plant may be set on the foot wall side of the vein, where it properly belongs, and in other cases it may be advisable to place it on the hanging wall side—this due usually to topography or to property lines. The ideal frame was described herein in the issue of June 10; but topographical conditions may necessitate a change from the detail of the frame there illustrated, while its principal engineering features remain the same. In that frame the idea of placing the shaft of the sheaves directly in line with the main compression members—the back braces—is advised. In the accompanying illustration, which is that of a

A New Zealand Head Frame.

frame at a coal mine in New Zealand, the sheaves are set directly on top of the posts. This peculiarity in design results in the compressive stress beginning at a point above the main compression members, but falling within them at the bottom of the frame. In general design the frame approaches that described in the issue of June 10, but actually it is more like that at the High Ore mine at Butte, Mont., which was also illustrated in that number. The other

illustration shows a head frame constructed under some difficulties of situation. It is a 2-post frame in Amador Co., Cal., and was built on a substructure of posts and cribbing, owing partly to the topography and partly to the nature of the ground, which was soft and offered poor support to the frame without these precautions. The hoist is situated on the hanging wall side of a vein dip-

A Two-Post Head Frame, Amador County, Cal.

ping at an angle of 50°. This frame was so constructed that it could be removed, if desirable, without any detriment to any of the timbers in the frame. No spikes were used in this construction. The timbers were framed with mortise and tenon and some members were dovetailed in, particularly the tie beneath the sheave and the upright posts supporting the sheave boxes. This frame is not represented as a high type of engineering, but as a frame of simple construction, which any carpenter can frame and build if given the design and dimensions. The frame after being in use several months was removed and set up at another mine.

The Treatment of Refractory Auriferous Sulphides at the Cassilis Mine, Victoria, Australia.\*

Written by FRANCIS B. STEPHENS.

The Cassilis mine, of which I have been manager for the last two years, made the first serious attempt to cope with the difficulties attending treatment of the refractory ores of that district, and a fair measure of success was met with, an extraction of about 85% of the value of ore crushed being obtained at a cost that compares favorably with those of mines treating much simpler ores.

While the ore at the surface in this district is very rich, giving returns of as much as ten ounces to the ton, there is a steady falling off in value in depth until at 600 feet the decrease in gold contents becomes serious. So marked is the falling off, accompanied by an increase in the refractory nature of the ore, that many of the smaller mines closed down after reaching 300 feet, and at the Cassilis improved methods of extraction alone permitted work to be continued at depth. The main body of ore comprises a band of dense sulphides consisting of arsenical pyrites, iron pyrites, zinc blende, galena, and carbonate of iron, while antimony, manganese, copper and tin occur in proportions usually of less than 1% each. The gold values range from one to ten ounces, averaging from three to five ounces, and a hand sample crushed and subjected to magnetic separation showed as follows:

Products of Magnetic Separation—	Per Cent by Weight.	Gold Per Ton Oz. Dwt.	Silver Per Ton. Oz. Dwt.
Pyritic concentrates (chiefly iron and arsenical pyrites).....	75.2	3 19	1 17
Quartz and gangue.....	18.3	Nil.	Nil.
Zinc product.....	3.6	2 5	2 12
Lead concentrates.....	2.9	0 13	0 14
	100.0		

The various minerals in this lode occur sometimes banded, but usually as a coarse mixture, and in places one of the minerals will occur in large masses to the exclusion of the rest. Large masses of galena and zinc blende are met with in this way. Lying next to this sulphide band there is usually a band of breccia

heavily charged with fine-grained arsenical pyrites and carrying about 7 dwts. of gold per ton; this is the most troublesome of all the minerals to treat, owing to the amount of slimes made in crushing.

Outside these two layers, and next to the country rock, the filling of the fissure consists of green talcose rock and green quartzite more or less charged with iron pyrites of low value. Large masses of mica

and talc are met with throughout the gangue, and crystals of andalusite occur in bunches. In the upper levels, where tourmaline granite occurs, the reef carries a considerable amount of tin, concentrates showing as much as 3%; in the lower levels no tin was noticed. Drilling in the sulphides liberated very poisonous gases, which sometimes drove the men away from the machines and brought on violent vomiting, no doubt due to arseniuretted hydrogen. In the outcrop orpiment (yellow arsenic sulphide) was common, and was usually a sign of richness; samples of pure orpiment have been obtained assaying up to sixty-two ounces of gold per ton.

The plant used for treatment consists of a jaw crusher, 16 by 9 inches, self-feeders, twenty head of 1000-pound stamps, silvered copper plates, four 3-cone hydraulic classifiers, six Wilfley tables and four Berdan grinding pans. Tailings go to settling tanks for future cyaniding, and concentrates are roasted for chlorination, while the galena is shipped to smelters after grinding. A drawback to chlorination in this district has always consisted in the large percentage of galena carried by most of the ores, and copper is also occasionally troublesome. Zinc blende after roasting is quite amenable to chlorination, our concentrates sometimes carrying 20% of zinc.

The galena is separated on the Wilfley tables and subjected to special treatment, thereby getting over the trouble in the furnaces due to fusion of the sulphides, a matter of some consequence with galena, running sometimes as high as 7% on the ore crushed.

The ore is crushed to pass an 18 by 20-mesh screen, and after crushing the pulp is run over silver-plated copper plates, giving a fall of 1 1/2 inch per foot to keep the plates clear of fine galena.

The amalgam yields a return of one-fifth to one-seventh of smelted gold. Before the employment of classifiers great losses of gold and mercury took place, but since their introduction the gold and mercury are caught in the galena streak on the Wilfleys. Only 20% of the total gold is obtained by amalgamation, though the concentrates show no visible gold on panning, except when rusty patches are struck.

Each five head of the battery have a series of three conical sheet steel hydraulic classifiers under a head of 20 feet of water, having diameters respectively of 12, 18 and 24 inches. The product from the four top-most compartments was run on to two tables, the middle product on to two, and the fines on to one table. When concentrates were made in heavy quantities, using a larger amount of water than was customary, an overflow to waste had to be made at the third cone to prevent flooding the Wilfleys, which before the introduction of classifiers had proved a serious trouble.

The Wilfley tables are set on very solid foundations, and all wear is taken up at once. To obviate any tendency for the wooden r file slats to buckle between the tacks and allow fine concentrates to pass into the tailings the slats are made of specially selected wood.

(TO BE CONTINUED.)

\*Trans. Inst. Min. and Met.

# Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 13, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROASTING FURNACE.—No. 792,053; F. Klepetko, New York, N. Y.

In furnace having one or more hearths, hollow rabble shaft and hollow arms thereof, conduits for directing current of air from shaft into hollow arms, and ribs disposed in path of currents traversing arms, ribs following general longitudinal dimensions of arms.

CHILIAN MILL.—No. 792,161; S. H. Pitkin and J. H. Stratton, Akron, Ohio.

Combination with pan or mortar having central bearing or hub, upper end of which is chamfered, of drive head, hollow sleeve passing through hub or pan of mortar and having feather-and-groove connection with drive head, spindle engaging drive head and having thrust ring for supporting latter, spindle having oil duct leading from upper end to point above upper end of hollow sleeve, short pipe for discharging oil in duct onto chamfered upper end of hollow shaft or sleeve, and flange on drive head and engaging driving shaft or sleeve for directing oil down to chamfered upper end of hub of pan or mortar.

METALLURGICAL FURNACE.—No. 792,223; J. W. Lansing, San Francisco, Cal.

Combination of furnace having plurality of upright interconnected furnaces each having normally closed ore chamber and firebox beneath ore charge, water-containing receptacle, connection between ore chamber and receptacle, stack separate from and devoid of connection with water-containing receptacle, connections between fireboxes of furnaces and

stack and valves in connections by which heat of furnace fires may be diverted from ore chambers, means for inducing draft through receptacle, and ore chambers and intermediate connections, and means for maintaining continued circulation of cooling fluid through receptacle.

DRILL.—No. 792,023; C. H. Haeseler, Philadelphia, Pa.

In combined hammer drill and feeder, combination, with feed cylinder and piston, of hammer drill secured to feed piston, feed cylinder having continuous passage extending from source of motive fluid supply to interior of hammer drill and including pressure area back of feed piston, throttle valve between pressure area and hammer drill for controlling hammer drill and throttle valve back of pressure area for controlling feed piston.

GOLD DREDGING MACHINE.—No. 792,250; S. L. Crawford and L. J. Crawford, Hoquiam, and W. F. Crawford, Bremerton, Wash.

In dredging machine, hood, casing supported thereby, and excavating mechanism arranged within hood and casing and having active portion operable in horizontal plane.

MECHANISM FOR LIFTING ROCK DRILLS.—No. 792,217; J. Jenkins, Lord, Md.

In rock drill lifting mechanism, combination with column bar, of cylinder and piston within column bar

having motive fluid inlet and outlet, drill casing and means connecting piston and drill casing for imparting motion from piston to drill casing.

TUYERE IRON.—No. 792,179; C. O. Swenson, Minneapolis, Minn.

Combination with tuyere iron fixed in forge and having lateral branch, and horizontal flange on upper edge, flange being formed with plurality of oppositely disposed segment shaped slots, of two parallel supports fixed in forge, one on each side of flange on upper edge of tuyere iron, and with upper surfaces aligned with upper surfaces of flange; rotary concave fire pot having horizontal flange, flange resting on flange of tuyere iron and on upper surfaces of supports, and bolts passing through bottom of pot and through slots in flange of tuyere iron.

ROTARY FURNACE.—No. 792,169; W. S. Rockwell, New York, N. Y.

Furnace comprising two communicating chambers mounted end to end, chambers being independently revoluble, means for supplying fuel to each chamber, door closing charging and pouring port in each chamber, second door closing port in each of first mentioned doors, and independent means for securing doors in closed positions.

METHOD OF CONVERTING GRANULAR OR PULVERULENT MATERIALS INTO LUMPS.—No. 792,449; E. Pohl, Harsum, Germany.

Process for converting granular or pulverulent materials into pieces or lumps, consists in roasting materials by introducing materials to be agglomerated at one end of revolving retort, injecting on materials binding substances and molten materials in finely divided state and discharge agglomerated materials at other end cohering pieces thus formed.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

"Le Moniteur du Potrole Roumain," of Bucharest, publishes the following table of the output of petroleum by the different countries in the past three years (tons):

	1901.	1902.	1903.
America.....	15,000,000	12,557,000	10,980,000
Russia.....	10,600,000	10,320,000	10,950,000
Sumatra, Java, Borneo.....	1,600,000	830,000	732,000
Gulfia.....	827,100	713,800	576,000
Roumania.....	496,800	381,300	310,000
India and Burmah.....	404,100	325,400	209,000
Other countries.....	250,000	250,000	270,000
Totals.....	28,577,100	25,380,500	21,027,000

The oil production of the world has shown a steady increase during the last three years, except in the case of Russia, which has only half recovered from its bad year in 1903. America and Russia together produced about 25 out of the 28½ millions produced in 1904. British India and Burmah have made the most notable increase in the three years, having increased 24% in 1904, notwithstanding that 1903 was an increase of 55% over 1902.

### ARIZONA.

A reconnaissance economic study of the mining districts of Arizona will be made by F. L. Ransome, assisted by W. H. Emmons during 1905. They will also make a detailed survey of the Tombstone district, including a special investigation of the mining areas. Topographic parties have been at work near Florence under the direction of T. M. Bannon. R. T. Evans will have charge of a party in the Grand Canyon which will survey the Shinumo quadrangle.

#### Cochise County.

(Special Correspondence).—The Calumet & Arizona Co. at Bisbee produced for the month of May 1336 tons. This has been the average production for each month since January. Sixty days later ore will be treated from the Oliver shaft of this company, but the production from the Irish Mag shaft will be correspondingly lessened. Extra jackets are en route from the East for the furnaces at Douglas. The big stack and the dust chamber are completed and the construction force is hurrying the completion of the dust flue. At the smelters a reserve ore pile of 5000 or 6000 tons is kept on hand, which, in the event of a shut down at the mines or a blockade of the Crook tunnel, is sufficient to keep the smelters in operation for seven days.

Bisbee, June 19.

Larrieu Bros. & Chadwick are sinking a 100-foot shaft on their copper property in the Whetstones, north of Bisbee.

#### Gila County.

J. B. Benton is superintending work, near Paradise, developing a water supply for reduction works in the treatment of ore. The shaft through the ore body is down 200 feet, with but little water.

#### Pima County.

(Special Correspondence).—The Imperial Copper Co., operating in the Silver Bell district, is shipping copper ore to the smelter at Douglas. During the last fifteen months, 12,000 feet of underwork has been done. A large boiler is being put in at the old Union shaft preparatory to starting work through this opening. A 10-ton experimental concentrating plant will be built at once and the necessary machinery to permit of the using of crude oil fuel in place of coal will also be added. Silver Bell, June 19.

#### Pinal County.

(Special Correspondence).—A mine on the Arizona-Pacific property, 7 miles south of Kelvin, has been opened by a shaft 320 feet deep and a crosscut at the 300-foot level. The shaft will be sunk several hundred feet deeper. Two 60 H. P. boilers, a 35 H. P. steam hoist, a 50 H. P. compressor and an electric lighting plant capable of furnishing 200 lights have been put in at Woolly, the Arizona-Pacific camp.

Kelvin, June 19.

The 14-mile wagon road from the railroad at Winkelman to the Saddle Mountain C. & S. Co.'s properties has been completed. The company is building a 200-ton smelter and developing bodies of copper ore.—The Troy-Manhattan Co. at Troy expects to have its 100-ton smelter ready to receive ore by November 1. J. W. Sisson, president, and J. W. Cameron are placing orders for machinery and equipment for the new plant.

#### Yavapai County.

(Special Correspondence).—The White Gold Mining Co., east of Wickenburg, is building a 10-stamp mill with a power plant large enough to permit of the addition of twenty stamps more should it be found advisable. They are also putting in a cyanide plant.

Wickenburg, June 19.

T. W. Earnhart is running the Monica mill at Kirkland.—I. Anderson has charge of building the new plant of the Anderson Metals Extraction Co. at McCabe.—G. W. Middleton of Prescott intends to put in a 350-ton concentrator at Walker to handle the output of the Mudhole and Crook mines.—The tunnel of the Sonator mine, 12 miles south of Prescott, is in 2000 feet.—It is reported that the Copper Bottom mine at Quartzsite has closed down.—J. G. Dennis of San Francisco, Cal., is unwavering the News group, near Jerome, preliminary to examination.—Superintendent Beven is unwavering the Black Hills Copper Co.'s mines near Jerome, preparatory to starting development work.

The Rincon M. Co., near Martinez, have started their new 40 H. P. hoist and are sinking in the main shaft. The new mill is expected to be running by July 15.

### CALIFORNIA.

In response to the memorial presented to President Roosevelt by the California Miners' Association, the United States Geological Survey has begun an investigation into the conditions affecting the hydraulic mining industry of the State. The motive that inspired the memorial was hope that gold now buried in the ancient river channels of California may be rescued by the hydraulic mining process, it being held by the miners that such deposits cannot be profitably worked by any process except hydraulic mining, now restrained by anti-debris legislation.

#### Amador County.

It is reported that C. J. Newman, manager of the Volcano G. M. Co., has handed the Bolden and Tierakoff mines near Volcano, and will work both properties. He is putting a 10-stamp mill on the Volcano mine, near the West Point bridge, on the Amador side of the Mokelumne river, and has thirty men grading for the mill and in the mine. The tunnel is in 700 feet.—The South and Central Eureka companies have entered into a pumping contract, by which a pump with a capacity of 288,000 gallons per day is to be put in at the 2000-foot level in the South Eureka mine. A reservoir is to be made capable of holding 50,000 gallons. All the water of the two mines is to be diverted by means of iron pipes into this reservoir, and pumped from there with one lift to the surface. The pump is to be driven with a 150 H. P. motor put in at the pump. The electricity to drive the motor is to be transmitted down the shaft through armored cable. In the Central Eureka drifting is to be commenced at the 2400-foot level.

#### Del Norte County.

Considerable work is being done on copper claims in the Preston Peak district, 20 miles south of Takilma, Or. J. F. Sanger is working properties in the district. C. L. Mangum of Grants Pass, Or., and J. R. Reeves of Waldo are also working claims. This district gives promise of producing copper when transportation becomes cheaper.

#### Lassen County.

J. W. Sexton, manager of the Salt Lake M. Co., which has purchased claims on Metal Mountain, says that twenty men will be put to work. The mine is 40 miles from Reno, Nev., and 2 miles from the N. C. O. Railway.

#### Mariposa County.

(Special Correspondence).—The Ferguson mine, near Hite's Cove, has been leased to F. Mason and E. Mason, who have started work at this old-time producer, which has been idle for several years.

Hite's Cove, June 19.

#### Nevada County.

The South Lindsay mine, near Maybert, is owned by the Syracuse & California M. Co. C. Meyers has charge of running a tunnel. The ore body has widened.—Work is to be started at the Banner mine, near Nevada City, in which C. M. Belshaw is interested. The shaft is down 700 feet.—Work has been resumed at the Graham gravel mine on Shady Creek, near Nevada City.—The Taylor iron mine, near Indian Springs, 11 miles from Grass Valley, is to be tested by a drilling machine.—Work is to be started at the Ironclad mine, near Rough and Ready. A hoist, pump and a gallow's frame are to be put in. The plant will be run by electricity. The shaft is to be sunk deeper by Superintendent Skewes.

The discovery of gold south of Donner lake, along the banks of the Donner creek, in a valley 4 miles long and 1 mile wide, is attracting people there.

Grading out for a new 10-stamp mill at the Morning Star mine at Badger Hill, 6 miles from Nevada City, has been commenced. The shaft is down 85 feet.—Superintendent J. H. English of the Spanish Ridge mine, 2 miles from Washington, reports that twenty stamps are pounding on ore. The company is running a lower tunnel, from which it is taking out good ore. A hoist is also put in.

#### Placer County.

Buchanan & Lozano are putting in a plant at the Bellevue mine, near Ophir.—At the Lundquist mine, near Auburn, a tunnel is being driven from both sides of the hill.—M. Repose has a bond on the Dunlap, below Auburn, and will prospect the ground.—The Jupiter gravel mine, near Iowa Hill, has closed down, because of lack of water.—Roht. Jones has men at work at the Cash Rock, near Forest Hill. This is a river claim, and the work has to be rushed to get to bedrock and take out gravel before the rains come.

#### Plumas County.

The Empire mine, at Gold Valley, 12 miles northeast of Downville, is being worked under the direction of T. K. Code, who has started the mill and has almost reached the 500-foot level in the shaft. The shaft is to be sunk to the 1000-foot level.

#### San Diego County.

The Julian Con. M. Co., operating the High Peak, Helvetia and Warlock mines, near Julian, are arranging to place all their stamps in one mill, instead of maintaining a separate mill at the High Peak. The company also intends to do its own roasting and reduction.—The Owens mine, near Owens, under the management of S. N. Large, is being put in shape to sink the shaft from the 350-foot level to the 600-foot level.

There are three different minerals that are mined for their lithium contents—lepidolite and spodumene (both lithium silicates) and amblygonite (a lithium phosphate). Of these three the last contains the highest percentage of lithia, but thus far has not been found as abundantly as the other two. The only locality at which the amblygonite has been found in quantity is near Pala. This deposit of amblygonite was discovered in 1902, but there was no production of the mineral until 1904. All of the lepidolite that is produced in the United States for commercial purposes is obtained in San Diego county, principally from near Pala. There are two localities in the county at which lepidolite has been found in considerable quantity, one being near Banner and the other 7 miles east of Julian. No lepidolite was mined at either of these localities during 1904, and only the necessary assessment work was done. The greater part of the

lepidolite has been exported, while nearly all of the spodumene has been utilized by home chemical manufacturers. From information obtained from the various chemical companies in this country that manufacture lithium compounds it is learned that there is an overproduction of these minerals for domestic consumption, and that unless some new technical use can be found for the lithium salts—as, for instance, their use on a considerable scale for pyrotechnical purposes—there must be considerable decrease in both the demand and the price for them. The mistaken impression has been prevalent that there was a large demand for lithium minerals, but with their use restricted principally to the manufacture of lithium carbonate the demand is bound to be limited. The quantity of lithium minerals produced in the United States during 1904 amounted to 577 short tons, valued at \$5155. This is a decrease of 578 short tons in quantity and of \$13,270 in value, as compared with the production of 1155 short tons, valued at \$23,425, in 1903. Of this 1904 production the greater part was spodumene from South Dakota.

#### Shasta County.

D. J. Robinson, manager, and J. B. McAfoos, assistant manager of the Pittsburg & Mt. Shasta G. M. & M. Co., are operating the Bennington mines in the Iron Mountain district, 14 miles from Shasta. The tunnel is in 320 feet.

At the Great Western Gold Co.'s copper smelter at Ingot, Superintendent H. Haas says that in the first concentration, with 2% coke on the charge, a matte with 30% to 35% copper is produced. This matte is broken, and reconcentrated (with two-thirds of green ore on the charge, and the necessary quartz and limestone) to a 45% or 50% matte, using 3% or 4% coke on the charge. The temperature of the blast is from 460° to 700° F. In the matte concentration the blast temperature has to be lowered to increase the copper content of the matte. An inclined track runs along the front of the large settlers, from which the matte is tapped into molds resting on a truck. The slag is granulated and sluiced over the dump. The furnace gases are drawn through a downcomer into the brick flue-chamber. The flue-chamber walls have wire-screen panels, covered with concrete about 1½ inch thick, and painted with silicon graphite paint to counteract the action of sulphuric acid, anhydride and sulphur dioxide on the oxyhydrate of lime found in Portland cement. The dust drops into the steel hoppers and is not taken up again by the gas current. Underneath the hoppers an 18-inch track is placed to remove the dust by means of cars, and to take it to the briquetting machine. The brick flue-chamber is 61 feet long and 16 feet high and 9 feet wide, and has a cross-sectional area of 60 square feet. The lower portion has arched openings, to give the air access to the hoppers and to keep the entire structure cool. It is on the bin-floor level. This arrangement obviates the necessity of elevating any flue dust. The furnace stack had to be extended to give the dowlake a pitch of 45° to prevent dust collection. The extension of the flue-chamber is a steel pipe, 21 feet by 250 feet, running horizontally for 40 feet under the railroad trestle-bridges, and then following the slope of the hill on which is built the stack, which is of sheet-steel, 5 feet 3 inches in diameter by 125 feet high. Inside the uptake pipe is the dust conveyor, which drags on the reinforced bottom trough (of ¾ inch steel plate) and delivers the collected flue-dust into the last hopper of the brick flue chamber.

#### Sierra County.

Work has been commenced on the Mountain View gravel mine, 4 miles above Alleghany. The old tunnel will be extended ahead to tap the gravel channel. T. F. Edwards of Forest City is in charge.

#### Siskiyou County.

It is reported that the Advance mine will put in a 10-stamp mill on China gulch near Yreka.—The Red Hill placer mine on South Fork is putting in a large flume.—A large new concentrator is being put in at the Taylor Lake M. Co.'s mill.—The dredge at Callahan started again. Several buckets have been added to the bucketway, that will enable the machine to handle the gravel much deeper.—The Ball mine, near Yreka, is being prospected, and a sale of it and the Stephens mines is about to be closed with Eastern capital. W. H. Young is handling it.—The Carson & Kradle mine at Oro Fino, operated by the Medina M. Co., has been closed down temporarily while a cyanide plant is being put in at the Johnson mill to handle the ore.

#### Tuolumne County.

The mill at the Golden West, in the Phoenix lake district, 5 miles from Sonora, has been started up.—The mill at the Rawhide mine, at Jamestown, has been started.—Work has been commenced on the mine at Astraville bonded by T. Cook to Mr. Monroe.—Sinking is in progress at the New Calico mine, near Stent, the shaft having passed the 150-foot mark.—W. Lewis has bonded a quartz claim on the Teeter ranch, near Sugar Pine, to H. J. Dykes, who has started work.—J. E. Conde and W. V. Connally have bonded the Murphy ranch, near Big Oak Flat, and have commenced work.—The Blue Star, West Star and Tar Flat mining claims, south of Tuolumne, have been bonded to H. Pennington of Reno, Nev.

### COLORADO.

During 1905 W. Cross, of the United States Geological Survey, will complete the geologic survey of the Lake City and Engineer Mountain quadrangles and make a reconnaissance of the San Cristobal quadrangle and of adjoining parts of Colorado, Utah and New Mexico, assisted by E. Howe, W. A. Emmons, A. Johansen, L. H. Woolsey and G. F. Kay. With the assistance of J. D. Irving, S. F. Emmons will make a review of the economic geology of the Leadville district. A reconnaissance survey of the Yampa coal field in the northwestern part of the State will be made by N. N. Fenneman and H. S. Gale. W. S. Ward will have charge of the collection of statistics of minerals in Colorado, with special reference to gold and silver. The Fort Collins and Boulder quadrangles will be surveyed by topographic parties, under direction of F. Tweedy. A party in charge

of J. F. McBeth will be engaged in topographic work on the San Cristobal quadrangle.

#### Clear Creek County.

The Muscovite on Democrat mountain, near Georgetown, has been bonded and leased to S. H. Clift and R. D. Smith of Denver, and it is reported that they have completed arrangements for development.—A contract has been awarded for driving the Central tunnel, at Idaho Springs, an additional 5000 feet to R. McGillivray. The breast of the tunnel is now in 4000 feet.—The shaft on the East Griffith, near Georgetown, is being sunk 200 feet deeper.—Work has been resumed on the St. Paul property, after a temporary close down caused by a change of management. The upper tunnel, which is in 1500 feet, is expected to penetrate the St. Paul lode within the next 50 feet. The property is on Green Lake mountain, near Georgetown. Frank Leitchweiss of Denver is the new manager.

A good strike has been made in the Tropic mine, on Seaton mountain, near Idaho Springs, by E. D. Quigley.

#### Chaffee County.

(Special Correspondence).—Near Buena Vista mines are being worked by the Elkhorn M. & M. Co., the Lashaw Tunnel Co. and the Stratton G. M. Co. The Lashaw Co. intend building an aerial tramway to transport ore from the crosscut into Princeton mountain, which is said to have cut good leads. The Stratton G. M. Co. is building a stamp mill to treat their free milling ore, and are sinking on their property. The Elkhorn shaft is being sunk to the 500-foot level; it is down 375 feet. They are also driving a 1000-foot drift from the 300-foot level. The drift is now in 400 feet and has cut good ore, carrying 2½ ounces gold, associated with pyrite and marcasite. The company intends shipping crude ore and may put in a mill. F. J. Frost is superintendent.

Buena Vista, June 18.

A. Ackerson, manager of the property in Pomeroy gulch, in the Chalk Creek district, near Buena Vista, has been in Denver getting boilers and an air compressor, to be put in at the mine as soon as the snow is gone.—This company has kept two shifts working by hand all the winter, and have their tunnel in 200 feet. The tunnel will be driven 1000 feet.—It is stated by the various managers and superintendents that the Camilla G. M. Co., the St. Elmo Con. who owns the Pat Murphy, the Buena Vista G. M. Co., Lone Star, New York & Colorado M. Co. and various lesser companies will all resume work within two weeks, as the snow is going rapidly.

#### Dolores County.

Electric power is to be put in at the Group Tunnel mill of the United Rico Mines Co. at Rico.—The Rico-Creede Co. is running its mill in Rico, having started the tramway.—The Intrinsic Gold M. & M. Co.'s tunnel on Sambo hill, near Rico, is in 1200 feet.—Atlantic Cable shipments from Rico continue regularly at the rate of from 80 to 100 tons of zinc ore per week. The air compressing plant is in place and the air drills will be started soon.

#### Gilpin County.

Manager O. J. Duffield reports another strike from the Maury tunnel of the Colorado M. Co., in Campbell gulch, near Perigo. The company expects to have its mill in shape to handle the lower grade ores by July 1.—The Victoria-Phoenix G. M. Co., which recently purchased the Crown Point mine, on Mineral hill, near Boulder park, is preparing to put in machinery at the main shaft.—L. A. White intends to resume operations on the Gold Spring tunnel property, west of Tolland.—The Mountain Monarch M. Co. is working in Gambell gulch, in the Independent district, with J. C. Barrows of Rollinsville as manager. The main tunnel is being driven under contract to cut the Seth Thomas vein. The Lump gulch mill will be put up on the Mountain Monarch millsite in Gambell gulch.

Manager T. J. Stroud of the Snowdon, at the head of Silver creek, near Apex, has unwatered his shaft and is drifting at the 100-foot level.—The Annie H mine and mill in Elk Park, near Apex, will be put in operation soon. New machinery and pumps will be put in the shaft. C. A. McNell will be in charge. Stuart & Murray, attorneys in the Continental block, Denver, are interested in the property.—C. A. Noack of St. Louis and H. Baer of Apex have begun work in the Baer group, near Black canyon, 1½ mile from Apex.

#### Gunnison County.

M. Gossman and N. Christenson are working the Navaho property, in Box Canyon district, near Pitkin.—At the Little Sister group, near Ohio City, R. W. Spensley will sink a shaft to water level.

#### Hinsdale County.

F. D. Goody is superintending grading for the cyanide plant to be built at the Golden Fleece mill at Lake City.—D. E. Sowers will work the Golden Wonder mine, on Gold hill, near Lake City, during the summer.

#### Ouray County.

The Bankers' National plant near Imogen basin, which suffered from a snowslide April 2, is in active operation, with a full force.

J. Koebel and P. Ochs are preparing to resume operations on their properties at the head of Bear creek, above Ouray.

A. E. Lowe, representing the New York stockholders of the Adelia M. Co., near Mineral Point, says that as soon as road conditions permit supplies will be taken to the mine and a larger force put to work. The mine has been operated all winter with a small force engaged in developing and sinking the shaft, which is now down 300 feet.

Manager W. J. Hammond, Jr., of the Treasury Tunnel M. & R. Co., at Ouray, is excavating for an additional twenty stamps; ten stamps are now at work, and ten more are on the road, giving forty in all. The plant will be run by electricity. In the mine and mill there are fifty-five men at work, but this is to be increased to 100. Manager G. Crawford of the Red Mountain R. M. & S. Co. states that development is being pushed at all the workings. The Genesee tunnel is 2300 feet under Red

mountain, and it has cut several leads. The east drift from the Genesee tunnel is 1000 feet on the vein. The Joker tunnel, in which the air drills were first started December 11, is pointed toward the Guston 1600 feet under the hill, and has made a good record for speed. The company's railroad from Silverton to Red mountain is being put in order and is in operation to Chattanooga.—In the Bachelor district on the Denver & Rio Grande, the Exum, Newton & Hurlburt lease in the lower workings of the Bachelor continues to output high grade ore.

#### San Miguel County.

Leasers are working the Suffolk-Globe at Ophir.—E. E. Bassett, L. Nielsen and F. E. Trimble have taken a lease on the Morning Star mine on Bilk creek, near Ophir, and have started work.—Recently the Carribeau mine, near Ophir, has been worked with half shifts, on account of bad air. Every year since the mine has been worked this has happened twice a year—June and September.

#### Summit County.

Work has been started on the Southern Cross lode in McCullough gulch, near Breckenridge, under the direction of M. W. Mouat.—M. M. Howe is ground-sluicing on the Star placer in the upper Blue River district, near Breckenridge, and hopes to start hydraulic mining with giants.—About fifty men are employed at the Snowstorm placer, at Fair Play. Washing of gravel will commence in a month. The tunnel will be 400 feet in length and will furnish the outlet for the water and debris from the new workings.—J. H. Myers, Jr., has started work in the Mint tunnel at Frisco.—The development on the Laurium, near Breckenridge, by Walker & Niles, has opened up sufficient ore to warrant them in starting a mill for the treatment of fifteen tons a day.

#### Teller County.

Lessee Schoonover of the Schoonover Leasing Co. has struck good ore in the New Discovery, 1 mile from Cripple Creek, and will put in machinery and a gallows frame.—S. B. Innskeep, who recently secured a lease on the Agnes property on the slope of Beacon hill, Cripple Creek, has made preparations for sinking the shaft for at least another 100 feet, and perhaps 400, the shaft now being 100 feet deep.—Operations on the Lillie mine, Cripple Creek, owned by the Vindicator Co., are being pushed by Lessee J. E. Bergeron. The main shaft of this mine has been sunk 1500 feet.—Manager Little of the Dexter Co. is in the East making preparations for leasing this property. The shaft is 600 feet deep, and provided a lease is granted one of the provisions of the contract will be that the shaft must be sunk to the 1000-foot point.—Machine drills are to be put in the Sellers lease on the Gold Dollar at Cripple Creek. W. P. Sellers is superintendent.—The new mill of the Little Giant M. Co. in Pony gulch, near Cripple Creek, is nearly completed. Manager C. Burch has arranged with H. R. Weber of the La Bella Power Co. for electric power.—The main winze of the Anaconda Co. at Cripple Creek is to be sunk another 200 feet, giving a depth of 580 feet below the main tunnel level.—E. A. Colburn has taken a five-year lease on the Oak claim on Ironclad hill, Cripple Creek.—The Western Investment Co., operating on part of the Specimen claim belonging to the Stratton Cripple Creek M. & D. Co., on Bull hill, has completed putting in machinery and ore bins and expects to start mining operations.—The cyanide mill being constructed on the Los Angeles claim on Bull hill, Cripple Creek, is nearing completion and it is expected that active work will be started.—J. O. A. Carper, who is operating the War Eagle on Bull hill, Cripple Creek, under lease, is drifting at a depth of 70 feet.—The Gold Sovereign Co. at Cripple Creek has started sinking the shaft an additional 100 feet, which will make the main shaft 800 feet deep.

### IDAHO.

During 1905 a geologic reconnaissance and mining investigation of the region north and east of the Cœur d'Alene mining district, will be made by F. C. Calkins assisted by D. F. McDonald, of the United States Geological Survey. A reconnaissance study of the economic geology of the Pearl, Hailey, Mackay and Ketcham mining districts in southern Idaho will be made by J. W. Boutwell. The mineral statistics of the State will be made by V. C. Helkes.

#### Blaine County.

Since June 1 the Wood River Zinc Co. has been running its new concentrating plant on the War Dance property, near Hailey. Manager Williams states that since the concentrator began work the only effort has been to adjust the tables and crushers. There are two waste dumps at the War Dance which accumulated while the former owners mined for silver and lead. All the work was on the vein, so that the waste is zinciferous ores and lower grade lead and silver which, with the crude appliances and conditions prevailing several years ago, was not commercial. The first milling of Manager Williams will be these dumps.—At the Eureka mines at Bullion, 7 miles from Hailey, work is to be resumed by W. A. Wilson.

#### Boise County.

In the Pearl district J. C. Johnson, manager of the Little Gem M. Co., is putting in a hoist and work will be resumed on the shaft.—In the Osborne a 5-foot vein of ore has been opened in the shaft at a depth of 200 feet. Experiments are to be made on a shipment to Denver to determine the best method of treatment.

#### Custer County.

It is reported that the White Knob mine at Mackay has been ordered closed, and that the equipment is to be sold.

#### Idaho County.

The Rainbow G. M. Co. is working on Sable creek, 3 miles from Roosevelt. The company intends to put on a 50-ton reduction plant if the ore values continue.—The Dewey mill at Roosevelt has been temporarily closed down for repairs and supplies.—The new Sunnyside mill, near Roosevelt, was started June 5. The tramway is working well. J. Treweek of Salt Lake City is superintendent.—The mill for the Mysterious Slide Co.

has been shipped to Roosevelt.—Chas. Werdenboff and sixteen others are preparing to work placer mining ground in Yellow Pine Basin in Thunder Mountain district. It is the intention of the owners to take in a drill for boring on the tract to determine where the best channels are located. A large ditch, capable of carrying 500 inches of water, is being built for prospecting purposes.

The Adams M. Co. has the foundation of its mill complete, also a number of new buildings. This property lies on Divide creek and over the ridge from Roosevelt toward Cooney.—The Fairview will begin work soon.

The Adams M. Co. is putting a 50-ton mill on the property known as the Barnett group, on Divide creek, Thunder Mountain district, near Roosevelt. H. C. Willis is manager.

#### Shoshone County.

In the Pine Creek district, near Kingston, the management of the Bobby Anderson intends to put in a hoist and pumps at the old 180-foot shaft and to develop the property. T. Brown of Kingston and H. Harrington of Kellogg are interested.—The new 250-ton concentrator for the Hercules mine at Burke is expected to be ready by Aug. 1. In connection with the mill the company is building a tramway to haul the ore from the mine to the mill. The tramway will start from the mouth of No. 3 tunnel, whence it will be built around the hill to 1600 feet above the mill, whence the ore will be carried by a gravity tramway.—The German-American Co., working the Phoenix, 2 miles below Oshurn, will put in an air compressor. W. P. Beldine is in charge of the work.—The Silver Star tunnel, 2 miles east of Mullan, is to be extended 100 feet. W. H. Batting is president.—E. P. Spalding, manager of the Monarch mine at Murray, states that the Monarch mill will close down as soon as the ore in the bins and chutes is cleaned up. This action is taken simply because the margin of profit is too narrow after hauling the concentrates to the railroad. The first work will be to run a tunnel which will open the vein 600 feet below its apex. Work will be resumed in the long tunnel, which gives 1400 feet depth on the vein. This tunnel, after being driven 3000 feet, cut the vein in a barren spot.—The Wonderful mine, on Stevens peak, near Wallace, will resume work.—The Horst-Powell Co. is preparing to ship copper ore from its mine on the Little North Fork, near Kingston. They are figuring on putting in a concentrator this year.—W. D. Church of Walla Walla, Wash., will start work on the Colwyn, on Sunset peak, and the Mexican group, near Gem.

### MONTANA.

W. H. Weed will complete his report on the Butte mining district during 1905. A reconnaissance investigation of the lignites in eastern Montana will be made by M. R. Campbell, assisted by A. G. Leonard. The geology and underground water conditions of the Sun River area will be investigated by C. E. Siebenthal. A study of stratigraphy and paleontology in western Montana will be made by C. D. Walcott. A Hague will complete his monograph on the Yellowstone National Park.

#### Beaverhead County.

O. H. Howarth, of the Royal Geological Society of London, and B. E. Peto have been examining the graphite mines near Dillon.

#### Deer Lodge County.

Several suits for injunction have been brought by ranchers in the Deer Lodge valley against the Anaconda and Wasboe Cos. to stop the operations of the Wasboe smelter at Anaconda. It is claimed by the ranchers that the sulphur smoke and poisonous fumes from the smelter are ruining the land and killing the live stock. The company has settled with a number of ranchers and paid them satisfactory prices for their land. The remaining land owners affected by the smoke formed an association and pooled their claims and then appointed a committee to fix the sums that each should demand from the company. In that manner the price was fixed and presented to the company for payment. The company found on investigation that the property appraised for taxation was less than 5% of what the owners demanded and refused to settle on that basis. The association then brought injunction suits and named the amount of their damages, multiplying the original claims by about three, or about 98% higher than the assessed valuation of the property. The company claims it is a scheme to force the company to settle at the price demanded or have the smelter shut down.

H. C. Bacon says of the Cable mine at Cable that formerly only the upper levels were worked and the water was allowed to accumulate in the lower, but they are now being prospected with two diamond drills.

#### Silver Bow County.

A new three-compartment shaft is being cut on the Leonard property, near Butte, owned by the Boston & Montana Co. They have found it necessary to make this improvement because of the condition of the old shaft, which has become twisted. The new shaft is being made from various points below, and at the present rate of progress will be finished to the 800-foot mark in a short time.—The shaft on the Minnie Healey is in the same condition as that of the Leonard. It is 1170 feet deep, 70 feet having been sunk recently to make room for the skip chute.

In Silver Bow county there are 1400 patented claims; 1257 are lode claims; 465 are owned by the companies and 944 by individuals; 127 mines are being worked, and of these 80 are owned by companies and 47 by individuals. The average production is 14,000 tons per day and 11,500 men are employed by the mines and smelters of Butte.

### NEVADA.

#### Lincoln County.

The Newport-Nevada M. Co. has found good ore at a depth of 175 feet on the Homestake mine at Fay. Superintendent E. H. Hackett will start the 25-ton mill and will raise to the surface from the tunnel.

In the Golden Treasure mine, at Searchlight, the

Quartette Co. has temporarily stopped sinking at a depth of 870 feet, while a chute is being cut from the 800 to the 850-foot point. The east drift on the 800-foot level is in 50 feet. All shipping ore is being taken from the 700-foot level.

The Keystone and Barefoot mines at Goodsprings have been consolidated. C. F. Schrader of Los Angeles, Cal., T. G. Wimmer and H. H. King of Salt Lake City, Utah, are interested.

#### Nye County.

J. McKane and C. M. Schwab have purchased the Great Eastern property at Bullfrog from J. Sellers for \$80,000. Work has been resumed on the North Star mine, at Tonopah, under the direction of D. B. Gillies.

The mill of the Tonopah M., M. & D. Co. has been temporarily closed down. The following mines have machinery at Bullfrog: Montgomery-Shoshone, cars, track and whim; National Bank, power gasoline hoist; Gold Bar, whim; Shoshone-Polaris, cars and track; Yankee Girl, gasoline hoist; Amethyst, hoist ordered; Original Bullfrog, cars and track; Ladd-Benson, cars and track; Peary-Montgomery, cars and track; Amargosa G. M. Co., whim; Rhyolite Townsite mine, whim.

J. P. Branioy, manager of the Primrose claims, 5 miles northeast of Beatty, has commenced work. The Hicks & Leavitt mines, 35 miles south of Beatty, have been bonded to T. L. Oddie for \$150,000. Supplies and men have been sent to the mines.

The Beatty mining district, which includes a large part of what is called Bullfrog, has been dissolved, the claim owners unanimously agreeing to merge the Beatty district with the Bullfrog district in order to prevent confusion in the minds of the public.

#### OREGON.

##### Baker County.

A 10-stamp mill is to be built at the Connor Creek mine, 20 miles down Snake river from Huntington. The old mine was one of the first quartz mines discovered and opened in eastern Oregon. P. Basche of Baker City is interested. The old tunnel has been retimbered and pushed forward until there is 4200 feet of tunnel work.

At the Bonanza mine, near Sumpter, twenty stamps at the mill are dropping and five machine drills are busy on the 200 level. A. Caso has been retained by the Geiser-Hendricks Co. as consulting engineer, and will have control of its properties. L. V. Swigget, manager of the Golden Chariot, near Sumpter, says that work will be resumed at the mine putting in the hoist and pumps, after which the crosscut at the foot of the shaft will be driven to connect with the ledge. The Oklahoma M. Co. has been organized to work property on Goose creek, near Sanger. The property was partly developed by C. C. Cox, who organized the company. F. D. Smith of Sumpter, manager of the Snow Creek mine, and operating the Psyche and the Diadem properties, near Greenhorn, says that both the Snow Creek and Psyche mills are running, the California gulch placer, belonging to the Snow Creek Co., is operating and development is being pushed.

The suit between the Turnagain Arm Co. and the California Mountain Con. M. Co. regarding the California mine at Cableville has been settled by a cash payment and turning over of stock. The California Mountain Con. M. Co. goes out of existence. D. L. Killen of Sumpter is treasurer.

The James B. Sipe M. Co. has been formed, with J. B. Sipe president and manager, T. Kennerly vice-president, W. C. Winterhalter secretary, C. L. Mobney treasurer and W. F. Kippen superintendent, to buy and work the Buckeye and the Great American Fraction groups, near Bourne. It is reported that Manager Stott will put in a reduction plant on the Lily mine, near Greenhorn.

##### Jackson County.

The Yellow Jacket mine, on Forest creek, near Jacksonville, is being worked by H. A. Mears and W. F. Shaffer, who have shipped a carload of ore to the Tacoma smelter.

##### Josephine County.

The American Gold Fields Co., W. J. Morphy president and manager, intends to add ten stamps to the mill at the Granite Hill mine, near Grants Pass, making twenty in all. L. Y. Wickersham is superintendent at the mine.

Deposits of variegated marble in the Cheney Creek district, 11 miles from Grant's Pass, have been sold by H. K. Hanna and Bull Bros. to J. E. Chappell, A. Baker and J. Atkinson, all of Goldendale, Wash., and J. E. Verdin and B. T. Bull of Grant's Pass.

#### SOUTH DAKOTA.

##### Custer County.

The Extreme Co., owner of the Minnie May property, 2 miles northwest of Custer, is unwatering the main shaft preparatory to making some tests on the ore and performing further development.

##### Lawrence County.

W. Santry of Stillwater, Minn., president of the Columbus Con. near Lead, states he is preparing to build a big mill on the Columbus, and would also put in mine hoists, compressors and pumps. The mine adjoins the Homestake on the northwest. Operations are going forward steadily at the Clover Leaf at Rouhaix. The water is held below the 500, so that ore is being stoped on and above that level. Forty stamps are dropping. P. Wihaux, president of the company, is at the mine, and expects to unwater the shaft to the bottom. Manager C. A. Allen has resumed work at the Lucky Strike shaft, southeast of Lead City. It is 200 feet deep, and is equipped with a steam hoist, air compressor and pumps. The first work that will be done will be to continue the east drift from the lower level 30 feet farther, where it is expected a vein will be cut. The Echo G. M. Co. intend to put in machinery at the Echo mine at Maitland.

The Goldstake M. Co. is developing a property in the Maitland district. An electric drill has been working on the crosscut tunnel, which is in 700 feet, and is to be continued to a depth of 1700 feet. O. U. Pryce of Deadwood is manager.

#### UTAH.

##### Beaver County.

(Special Correspondence).—Marshall Field & Co. of Chicago have a sixty-day option on seventeen claims belonging to W. L. Croff of Eureka, Utah. These claims are in the Lincoln mining district and are within 8 miles of the Majestic smelter at Milford. The option is for \$80,000. Lead is said to have been discovered in this district in 1858. Several thousand dollars has been spent in development work.

Milford, June 19.

##### Juab County.

(Special Correspondence).—The old Bullion-Beck and Champion property is being worked mostly by leasers, 100 men being employed on lease account, and \$10,000 per month being taken from the forty blocks of ground now under lease. The company under Superintendent L. C. Doty is operating four machine drills doing development and prospect work. J. P. Hannifin, superintendent of the Little Chief M. Co., is doing prospect and development work. He has some ore, but not making any effort to take it out. He is using machine drills. The Snow Flake, which has been idle for the past two years, is being put in shape to start operations. It is understood now boilers will be installed later on. J. B. Evans is superintendent and W. Hatfield of Salt Lake City is manager.

The Uncle Sam Con. M. Co. is a consolidation of the Humboldt, Richmond, Anaconda and Uncle Sam. The Richmond and Anaconda are being worked by leasers and the Uncle Sam by the company. The 100-ton concentrating mill which was built by the company some time ago as an experiment is proving to be a good investment. The ore taken out with the shipping ore that is too low grade to ship is put through the mill. No attempt is being made at present to mine mill dirt except that which is taken out with the smelting ore. The ore is sorted in the mine. There are heavy streaks of mineral running through the mine which permits them to sort the first grade ore from the mill dirt without trouble. The expense of milling the first year was \$1.24 per ton, divided as follows: Labor, 53 cents; repairs, 27 cents; power and water, 34 cents; superintendent and assaying, 10 cents; total \$1.24. Twenty-one thousand tons of ore were put through the mill the past year, with an average assay value of 6.6% lead, 5.1 ounces silver and a trace of gold. From this amount of ore they produced 2944 tons of concentrates, with an average assay value of 38.3% lead, 20.8 ounces silver, \$2 gold, which shows an average saving in the mill of 83.8% lead, 58.2% silver. This saving is based on the selling of the concentrates as denoted in the smelter samples. The mill is operated eight hours daily. The hoisting plant, which was destroyed by fire last summer, has been replaced by a new plant. Eight thousand dollars has been spent the past year in development work in the mine. The production for the year shows 40% on the total production of the mine, according to General Superintendent C. C. Griggs. During the past year the company paid \$20,000 in dividends and another dividend ordered. Several more Callow tanks will be put in the mill. The officers of the company are: J. Dern, president and general manager, Salt Lake City; J. Chipman, treasurer and vice-president; W. Thompson, secretary; C. C. Griggs, general superintendent; W. M. Carter, mine superintendent; J. C. Jensen, mill superintendent.

H. M. Eakin, superintendent of the Mayday at Eureka, has been shipping twenty cars of ore per month until recently, as development work is being done instead. A 100 H. P. boiler has been put in, which will give power for operating the drills. The tunnel is 750 feet in length. The hoist, which is over a 300-foot shaft, is in the tunnel. Prospecting is being done on both the 200 and 300 levels. The ore occurs in pockets, and as soon as a pocket is worked out it becomes necessary to do prospect work for other bodies of ore. They are operating four machine drills. J. Roundy is superintendent of the La Reine M. Co., and has started drifting from the 300 shaft.

Eureka, June 19.

(Special Correspondence).—Near the head of Grand Central gulch, near Mammoth, the Grand Central mine, under the management of P. J. Donnelly of Eureka, is equipped with steel shaft buildings and steel head frames over a 1300-foot double-compartment shaft. They are taking out ore from the 1300 level. Ore being taken out at present averages \$20 in gold and 30 ounces silver. The mine is equipped with four 100 H. P. boilers, Ingersoll compressor and Cooper Corliss engine. They are operating ten drills and shipping twenty-five to thirty cars of ore per month. The 3-mile aerial tramway extends from the mine to the R. G. W. and S. P. L. S. & S. L. railroad tracks, and has a capacity of 150 tons per day, but at times they have carried over 200 tons in a day. They have recently finished sinking the shaft from the 1100 to the 1300-foot level. There are drifts from the second level down to the 1300 level. The output from the Carisa at Robinson is about 1000 tons per month. Most of the work is done by leasers. The company has a few men at work sinking a winze and doing other work. E. Hoffman is superintendent. J. Roundy of Eureka has charge of the work on the Black Jack, which joins the Lower Mammoth and Ajax. The shaft is down 1400 feet and work is being done on the 300, 1000 and 1300-foot levels.

S. McIntyre, superintendent of the Mammoth mine at Mammoth, is working 160 men. On account of a liberal contract with the United States S. Co. he is enabled to ship ore that heretofore was thrown over the dump. The company is the owner of a large mill on the railroad at Robinson, but on account of the nature of the ore they have never been able to treat it successfully through the mill. The shaft is down 2100 feet and levels each 100 feet. The tunnel is in 500 feet and connects with the shaft. The ore is brought to the tunnel level from the lower levels and brought out through the tunnel to the ore bins. The ore bins are on the tracks of the R. G. W. Ry. They are shipping 100 tons per day. Mammoth, June 20.

Work will be started on the West Mammoth and Golden Ray claims, owned by H. Deprezin of Eureka.

T. F. Singheiser of Salt Lake has a bond, the conditions of which are that work must be commenced before July 1. W. W. Matthews has charge of the work. The ore shipments from the Tintic district for the week ending June 17 were: Eagle & Blue Bell, 11 carloads; Yankee Con., 7; Ajax, 2; Carisa, 3; Grand Central, 7; Mammoth, 12; Victoria, 3; Centennial Eureka, 43; Gemini, 6; Bullion-Beck, 2; Monterey, 1; Swansea, 7; Uncle Sam, 1; South Swansea, 1—total, 106.—G. Paxman and D. Porter are operating a jigging plant at the South Swansea dump at Eureka. H. Waters and W. McDonald are shipping ore from their lease at the La Clode mine, near Silver City. It is reported that the company will resume work at the La Clode, with W. Frazer in charge. S. Waro is hoisting thirty tons of ore daily from the Swansea mine at Silver City. No work is being done below the 800 level. The Eureka Hill M. Co. will lease a portion of the old workings of the old Eureka Hill mine at Eureka. Superintendent Paul Troester says that the leasers will be allowed everything above the 100-foot level. The trouble over the consolidation of the Raymond and Illinois properties, north of Eureka, has been settled and work will be resumed. President J. C. Sullivan has called a meeting for June 26. It is thought that the development of the ground will be started July 1, to be carried on through the Raymond shaft, which is down 1500 feet. The tunnel at the McKinley M. Co.'s property at Eureka is in 645 feet.

##### Summit County.

It is reported that work is to be resumed at the Great Western and Mountain Lake mines, between Park City and Brighton, owned by D. Evans and J. Knight.

##### Tooele County.

(Special Correspondence).—The Consolidated Mercur mine at Mercur has three veins, one above the other. At times these veins lie flat and at other times dip. The veins vary in thickness from 8 to 10 feet, and at other places are 30 to 40 feet in thickness. The ore in the lower vein is oxidized and the middle and upper veins have both base and oxidized ore. The middle and upper veins have been worked since the mine was started and no attention was ever paid to the lower vein until the past year, since which time Manager G. H. Dern has done considerable work. Most of the ore is coming from the two upper veins and from places where the ore was believed to have been worked out. The "caving" system is used quite extensively in this property. A large amount of the work in the mine is driving drifts through old and caved workings. Wherever possible they are mining in open cuts by making chutes and allowing the ore and dirt to pass down to the lower or tunnel level, and from the chutes into cars. The cars underground are assembled by a horse from the different drifts to the electric tunnel or main entrance to the mine, and from there the electric motor takes them to the incline, which runs from the top of the mill to the tunnel level. The ore is hauled in skips from the ore bins below to the top of the mill. These skips hold about three tons and are hauled by means of a double drum hoisting engine. Five hundred feet of this track is on an incline of 45°, while the remaining 200 feet is perpendicular. About 800 tons are being treated in the mill at present. At the mouth of the electric tunnel is a sampling mill, where the ore is sampled from all parts of the mine.

One of the main industries of the Sacramento G. M. Co. at Mercur is the production of quicksilver. Within the past two years this company has shipped four carloads of quicksilver to different sections of the country, as well as filling local orders. They can handle 2500 pounds of ore, less the moisture, in their three retorts, but are putting in three more retorts, which will enable them to double their capacity. They are handling 140 tons of ore through their cyanide mill. The ore from which they extract the quicksilver also contains gold, but they cannot extract the gold values without roasting before cyaniding. When the tailings dump from the quicksilver retorts becomes large enough they will probably put in a plant to handle the dump to extract the gold values. G. W. Coeber is mill superintendent and E. W. Jones mine superintendent.

On the line of the Salt Lake & Mercur Railroad, between Fairfield and Mercur, the old Mercur or Manning mill is being operated on the old tailings dumps. These dumps were formerly handled by this cyanide mill. The ore or tailings is hauled to the top of the mill and thrown into bins. It is then drawn off and distributed to the leaching tanks, where it is allowed to leach from twelve to eighteen hours before being treated in strong solution. It requires three days to finish leaching. C. P. Briscoe, superintendent of the plant, says the total cost to treat the ore is 42 cents per ton. The ore does not have to be recrusbed. G. W. Gillman is metallurgist. Mercur, June 20.

#### WASHINGTON.

##### Clallam County.

According to R. Arnold, Clallam county, on the Olympic peninsula, in the northwest corner of Washington, contains two fields where coal occurs in apparently workable quantities. A small quantity of coal was shipped from one of the fields a few years ago. However, not much development work has been done since, and it remains for future exploitation to determine whether or not the deposits are of economic importance. One field lies in a synclinal trough immediately south of Freshwater bay. Its detailed structure, however, is imperfectly known, owing to the glacial drift which covers most of the country rock of the region. The presence of coal in this field was disclosed by a drill hole, which cut through three seams, as follows: A 4-inch bed at 40 feet, a 26-inch bed at about 250 feet and a 56-inch bed at 525 feet. The quality of this coal is said to be similar to that found in the Clallam bay field. The second field lies between Pillar Point and Clallam bay, and it also occupies a syncline. The structure of the basin is more or less complicated by sharp local folds and faults which may interfere with the working of the deposits. Three seams have been found in this field, the main one being 36 inches thick, while above this is a 22-inch bed and below it a 12-inch one. The coal is a clean, hard, glossy, black lignite, which breaks with a conchoidal fracture and contains some pyrites. According to M. R. Camp-

bell, this lignite is particularly well adapted for use in gas producers. The local demand for coal in the county is small. It therefore will have to be shipped if mined in very large quantities. A factor in favor of both fields is their nearness to the navigable waters of the Strait of Juan de Fuca. The coal, after mining, can be loaded immediately on sea-going vessels, thus doing away with much of the expense of handling and bauling to tide water, which is added to the cost of mining in the case of the other Washington coals with which the product of the Clallam county fields will necessarily come into competition.

## FOREIGN.

### CANADA.

#### BRITISH COLUMBIA.

##### Boundary District.

For the week ending June 17th the tonnage from Boundary mines was: Granby mines to Granby smelter, 11,289 tons; Mother Lode to British Columbia Copper Co.'s smelter, 3712 tons; Mountain Rose to British Columbia Copper Co.'s smelter, 66 tons; Oro Denoro to Granby smelter, 66 tons; Providence to Trail smelter, 30 tons. Total for week, 15,663 tons; total for year, 425,955 tons. Boundary smelters for the last seven days treated as follows: Granby smelter, 12,808 tons; British Columbia Copper Co.'s smelter, 4286 tons. Total for week, 17,076 tons; total for year to date, 447,350 tons.

##### Kossland District.

The winze from the ninth level of the Centre Star is 150 feet below the ninth level, or about 1400 feet from the collar of the shaft.

The shipments for the week ending June 17th were: Le Roi, 2050 tons; Centre Star, 1860; War Eagle, 1290; Le Roi No. 2, 120; Jumbo, 100. Total for the week, 5420 tons, and for the year, 157,194 tons.

##### Vanconver Island.

(Special Correspondence).—The Tye Copper Co.'s smelter at Duncan's Station ran 8 days during May and smelted 1501 tons of Tye ore, giving a return, after deduction of freight and refining charges, of \$23,070. The short run was due to installation of new machinery. Duncan's Station, June 17.

##### West Kootenay District.

The compressor for the Silver Dollar mine, on Mohawk creek, near Beaton, is being put in place. Water power is to be used for driving the plant. The pipe, 18 inches in diameter, is of wooden staves wound with galvanized iron wire and is coated with pitch. Timber is being hauled to the Beatrice mine, on Mohawk creek, and as soon as some of the timbers in the mine have been replaced and new work timbered, mining operations will be resumed.—The plant of the Silver Cup, at Five Mile, has been started and an upraise is being driven on the Sunshine tunnel.—Work has been resumed at the Oyster-Criterion mine.

### MEXICO.

The following money is minted by the Mexican government: Gold, 10 and 5 pesos; silver, 1 peso, 50 cents, 20 cents and 10 cents; nickel, 5 cents; bronze, 1 cent. The minting of money for private parties has been suspended, except for exportation. Fractional currency is legal only to the amount of \$20 in each payment of \$1000. Obligations contracted to be paid in foreign currency are paid with their equivalent in Mexican money at the rate of exchange prevailing on the day of payment. There is a reserve fund constituted of \$10,000,000 to regulate the circulating currency. This law went into effect in May, 1905, but the free coinage of silver ceased on April 16, 1905.

##### Chihuahua.

The American S. & R. Co. have work started on the San Antonio mine at Eulalia. — J. C. Brooks of Chihuahua is operating the Socorro mine and mill for J. W. Pender, near Sahuayacan. — Garcia & Arellano of the Chihuahua Exchange Co. have bought the Beneficencia claim in Santa Eulalia. — Ryan & Wilson, who have the option on the American mine in Terrazas, have decided to put in a new and larger pump, as they are convinced that the water can be banded. — W. C. Greene has bought the Harlan mine at Cocheno. — It is reported that as depth is reached in the Cigarrero mine, in Cerro Almoleza district, copper is coming in. It is believed by some that with depth that camp will change from lead to copper. — The pumps have been started on the Prieto mine in Parral. This mine has been leased by B. Gilpin of Los Angeles, Cal. — The narrow gauge railroad from the Chihuahua & Pacific's Guerrero Valley Extension to the Calera zinc mine, near Minaca, has been put in operation, and ore is being banded down to the main line for shipment. — At Dolores the Dolores Mines Co. has five stamps of its fifteen in operation and the cyanide plant is not completed. — L. A. Dockery and J. McDonald are doing development work on their property near the Dolores.

##### Durango.

T. S. Austin, chief metallurgist of the American S. & R. Co., has begun work on the 2000-ton smelter to be built at Velardena.

##### Guadalajara.

High-grade ore has been struck in the Santo Domingo mine, near Etzatlan, the property of the Amparo M. Co. of Philadelphia, which has doubled its shipments to the smelters, now shipping two carloads per day.

##### Guanajuato.

The La Luz M. & T. Co. is said to be preparing to drive a tunnel 12,000 feet long at a depth of 1400 feet to reach and unwater the La Luz, Bolanitos and other groups in Guanajuato. The mouth of the tunnel will be within 12 miles of Silao, and it will be for transportation as well as drainage purposes. J. C. Stewart is president of the new company, and the chief engineer is G. B. Burbank, who had charge of the work of harnessing Niagara Falls.

##### Jalisco.

E. J. Callahan has bought the Barranca mine, 10 miles

from Ameca, Jalisco, and has organized the Bonanza M. Co. to exploit the mine. T. Savage of Sunbury, Pa., is president, C. Sidler of Sunbury, Pa., is secretary and treasurer, and E. J. Callahan is general manager.

The Cuale M. Syndicate, in which H. L. Choistry and L. K. Purdon of Guadalajara are interested, is pushing development work in the Las Bolas mine in the Cuale district. A tunnel started by a Mexican company ten years ago is being continued.—Hydraulic machinery is being put on the property of B. H. Hammatt, in the Pihuamo district. The water supply is to be secured by constructing a dam across the Belem river and piping the water 3 miles to the placer field.—The Trinidad M. Co. has put in an air compressor and drills on its property in the Parnaso district.—A cyanide plant is to be put up at the San Felipe mines in the Hostotipanguillo district. Two concentrators were recently installed, but it has been demonstrated that cyaniding is necessary to secure the full values from the ores.

N. W. Kinross, manager of the Chatterton M. Co., has bought a one-half interest in the San Antonio y Anexas mines at Talpala and has agreed to spend \$100,000 for machinery and a reduction plant for the mines.

##### Oaxaca.

The Teziutlan C. Co. has purchased the Ocotes mines near Ejutla.—The Penoles M. & Dev. Co. has taken over seven old mines in the Penoles. The principal values are in gold. The Pilot Point M. Co. has completed a 10-stamp mill on its property, near Chibique, and development work is in progress. J. F. O'Connor of Dallas, Texas, is president.—A 10-stamp mill is being operated by the Mexican-American G. M. & M. Co. in the Sierra Juarez district.—The Mexico G. & S. Co. will import mining and milling machinery for its mines at Santiago Minas.

##### Sonora.

The Sonora G. M. Co., D. B. Maxwell manager, has acquired the Germania mine at Minas Prietas and is sinking two shafts.—At Promontorio the Promontorio Con. M. Co. are sinking a double-compartment shaft, which is down 200 feet. — Near Moctezuma the York mines have been bonded to a syndicate represented by O. L. Meer, manager Transvaal Copper M. Co.

The Garretson Sabuaripa Co. expect to blow in a 60-ton copper smelter at La Calera, Sabuaripa district, on July 1. Charcoal will be the fuel used.

The Sonora M. & D. Co. is operating the Dewey graphite mine near Hermosillo. S. W. Forsman is manager. The graphite occurs as a blanket deposit and was first found in opening up the ground to determine its merit as a copper property. The graphite as mined is sorted and screened to 1/4-inch for shipment. The shipments last year amounted to 400 tons. A double-compartment shaft sunk 135 feet on a copper ledge is being continued.

### NEWFOUNDLAND.

The mineral production of Newfoundland is reported by the Geological Survey of the Island as follows, for the year 1904:

Product.	Quantity.	Value Exported.	Total Value.
Barite, tons.....	2,000	\$ 4,750	\$ 5,000
Brick, thousand.....	1,236,000	.....	11,432
Building stone, tons.....	3,100	.....	4,550
Cobble and spawls, tons.....	4,000	.....	2,000
Copper ore, tons.....	107,839	395,723	466,739
Gold, ounces.....	11	.....	269
Granite, tons.....	1,945	.....	11,550
Iron ore, tons.....	589,739	585,739	589,739
Petroleum, barrels.....	700	.....	1,134
Pyrite, tons.....	60,200	210,700	210,700
Sand and gravel, tons.....	3,320	.....	5,800
Slate, tons.....	2,700	37,500	37,500
Talc, tons.....	1,562	7,000	7,000
Not specified.....	.....	200	200
Totals.....	.....	\$1,241,912	\$1,353,953

The ton used is the long ton of 2240 pounds. The total value for the year shows an increase of \$84,148, or 6.6%, over 1903. The number of persons employed was 2375—of whom 1131 were engaged in iron mining, 569 in copper mining, 285 in pyrite mining and 273 in quarrying. There were 4 persons killed, an average of 1.7 per 1000 employees.

## Personal.

W. C. RUTTER of Seattle, Wash., has been at Granite, Or.

C. E. RUEGER of Butte, Mont., has been examining mines at Phoenix, B. C.

J. S. GROW is superintendent Blue Jay copper mine, 20 miles from Stateline, Nev.

A. M. CARPENTER of Denver, Colo., is superintendent Takilma smelter at Takilma, Or.

W. G. LEWIS of Golden, Colo., succeeds J. F. Vivian as Surveyor General of Colorado.

H. SCHIELER of Weiser, Idaho, is superintendent Thunder Mountain & Big Creek M. Co.

J. E. SATTERLEY has been appointed superintendent Mass Con. mill at Grosse Point, Mich.

P. ARGALL of Denver, Colo., has been examining tin deposits in western Lawrence Co., S. D.

T. W. MACK of San Francisco, Cal., has been examining mines near Parral, Chihuahua, Mex.

H. A. MCQUEEN has been appointed assistant superintendent Rawhide mine at Jamestown, Cal.

D. J. FREW, secretary Holderman Filter Tank Co., of Salt Lake City, Utah, is in San Francisco, Cal.

N. I. LEYDIG has taken J. W. Ingersoll's place as superintendent Dakota mill at Deadwood, S. D.

E. J. CALLAHAN is manager Bonanza M. Co., working the Barranca mine, near Ameca, Jalisco, Mex.

W. S. KELLEY has resigned as manager Tintic M. Co.

and Yampa Smelting Co. at Bingham, Utah, and will devote his time to private interests.

T. J. GRIER, general superintendent of the Homestake mine, at Lead, S. D., has been in Chicago, Ill.

E. A. HOBART has resigned as superintendent mines of Pittsburg & Montana Copper Co. at Butte, Mont.

JAS. W. NEILL, who recently returned to Salt Lake City, Utah, from Butte, Mont., is in San Francisco, Cal.

F. J. TOUSSAINT has returned to La Cbumata mine, Arizona, Sonora, Mex., from a month's visit in Milwaukee.

C. E. CLAPP has resigned as director and fourth vice-president of the Crucible Steel Co. of America at Pittsburg, Pa.

J. M. THOMAS, superintendent at El Tiro mines of the Reina de Oro M. Co., Sonora, Mex., is visiting at Painesdale, Mich.

WM. ARNOLD of Butte, Mont., has been appointed assistant superintendent United Verde copper mine at Jerome, Ariz.

J. W. INGERSOLL has been appointed superintendent Hidden Fortune mill, near Deadwood, S. D., vice F. Steele, resigned.

T. A. RICKARD has resigned as editor of the Engineering and Mining Journal, the resignation going into effect on June 30.

F. YOUNG has been appointed superintendent Gold Reef Co., near Gilt Edge, Mont., succeeding J. H. McCormick, resigned.

R. B. LAMB has returned from Leonora, Western Australia, to accept a position with the American C. Co. at Encampment, Wyo.

H. A. SHIPMAN, superintendent Lake View Consols, has been transferred to the Oroya-Brownhill, Kalgoorlie, Western Australia.

WM. MAGENAU has been examining mines in western New Mexico. He is now associated with the Luna Lead Co. of Deming, N. M.

P. GAUDIN of the San Francisco del Oro mine at Santa Barbara, Chihuahua, Mex., is in France reporting on the property and will return in three months.

F. E. STEELE of Deadwood, S. D., has resigned as superintendent Hidden Fortune mill at Lead, S. D., to become manager of the new plant of the Victoria G. M. & M. Co.

S. NEWHOUSE of Salt Lake City, Utah, has been appointed managing director Montreal & Boston M. & S. Co. at Greenwood, B. C. W. C. Thomas has been made superintendent of the smelter and T. R. Drummond resident manager.

## Obituary.

CLARENCE HYMER, superintendent of the Hymer mine at Red Lodge, Mont., was killed in the mine June 9 by a heavy wheel falling on the back of his head.

HENRY BEGLINGER, one of the pioneer miners of Nevada county, Cal., died at North San Juan, June 20, aged 83 years.

TELEGRAPHIC REPORT from Mentor, Ohio, tells of a dreadful railway disaster at Mentor on the 21st inst., the N. Y. Central limited train dashing into an open switch while going a mile a minute. On board the fated train were Thos. R. Morgan and Chas. H. Wellman of the Wellman-Seaver-Morgan Co. of Cleveland, Ohio. The dispatch of the 22nd inst. states that Mr. T. R. Morgan was burned to death and that Mr. C. H. Wellman was scalded and burned to such an extent that it is feared his injuries will prove fatal.

## Books Received.

"The Fluorspar Deposits of Southern Illinois," by H. F. Bain, Bulletin No. 255, of the United States Geological Survey.

The United States Geological Survey has issued as extracts from "Mineral Resources of the United States for 1904," "The Production of Lithium Minerals," "The Production of Barytes" and "The Production of Asbestos."

Text books and other books of reference which treat on practical subjects in a practical way are valued by working engineers more highly than theoretical treatises. "Haulage and Winding Appliances Used in Mines," by Carl Volk, is a book of this kind. It is translated from the original German by Charles Salter. This latest contribution on the subject of hoisting in mines deals with the subject in a thoroughly practical manner, the author having omitted much of the theoretical side of the proposition. Hoisting ropes of the various types used, and their manufacture, together with the various devices for securing ropes to skips, cages, etc., is treated in the opening chapter. Then follows a discussion on the methods of underground transportation to the shaft. This includes tracks, switches, turntables and plates; the cars, and other vehicles, used in handling ore from slope to shaft; dumping devices, and the various conveniences employed in ore and rock handling in the mine. The chapter on cages and their construction, with safety devices employed, is interesting, and contains numerous practical suggestions. Shaft equipment and chairs also find a place here. It is unfortunate that so little space is de-

voted to the description of automatic or self-dumping skips, as these in many mines are taking the place of cages, it being recognized that ore may in many cases be handled more economically by skips than on cages. Considerable space is given to winding engines, for both vertical and inclined shafts, and this portion of the book is one of its most interesting and valuable features. Traction in mine levels is included, and goes into considerable detail in describing the various methods of haulage on level tracks and on those of low inclination. A short chapter is given to pneumatic hoisting, a method not as yet introduced in America, and used to only a limited extent in Europe. The aerial tramway, as applied to underground transportation, is described, as also is the various kinds of power applied—steam, water, air and electricity. An interesting section of the book is that describing "downhill haulage," that is, where ore or rock is to be sent from a higher to a lower level, in which the force of gravity is often utilized as a means of power. On the whole, the work is one that will prove useful to the student and mine superintendent, who is not "up" in mechanical engineering. It is published by D. Van Nostrand Co., 23 Murray street, New York, and by Scott, Greenwood & Co., 19 Ludgate Hill, London E. C., Eng. It will be sent to any address by the MINING & SCIENTIFIC PRESS upon receipt of the price, \$4.00.

## Commercial Paragraphs.

THE Salt Lake Hardware Co., Salt Lake City, Utah, have recently shipped to the Canadian Government one of their Kellor assay balances for use in the Geological Department, and also one to the Bureau of Weights and Measures for the United States Government at Washington, D. C.

THE Calkins Co. of Los Angeles, Cal., have acquired the corner in the Baker Block, Ardenia and Main streets, for their general offices and salesrooms, retaining their zinc shavings factory and chemical warehouse at their present quarters, 608 N. Main street. They propose to carry a full line of mine and laboratory chemicals and supplies.

THE Compressed Air Machinery Co. have an additional order from the Oliver Iron Co. of Duluth, Minn., for three Word Bros.' drill making and sharpening machines, making seven so ordered. They also have a similar order for one Word Bros.' machine from the Colby Co., Bessemer, Mich. Those machines furnish satisfaction wherever used. The Compressed Air Machinery Co., 24-26 First street, San Francisco, Cal., are sole manufacturers of this drill sharpener.

THE Rix Compressed Air Co. of 396 Mission street, San Francisco, Cal., report the sale to the California Gas & Electric Corporation, for the Oakland Gas Light & Heat Co., of two Laidlaw-Dunn-Gordon Cincinnati gear, heavy duty duplex compressors, each with a capacity of 100,000 cubic feet per hour at 20 pounds pressure, and one 12x18 booster, of same make, to boost portion to pressure 80 pounds, all to be driven by electric power. These are to increase the gas pressure in the mains. A similar plant, but of half the capacity and driven by Otto gas engines, has been sold to the Sacramento Light & Power Co. C. D. Lane has bought a 12-drill Laidlaw-Dunn-Gordon Cincinnati compressor and new style Torpedo drills for mines at Solomon, Alaska.

THE Ingersoll-Sergeant Drill Co. and the Rand Drill Co. have been united into a new company called the Ingersoll-Rand Co. The new corporation was formed under the laws of New Jersey with a capital of \$10,000,000, of which \$5,000,000 is preferred stock and the balance common. The factories of the two companies are located at Phillipsburg, N. J., Easton, Pa., Tarrytown, N. Y., Ossining, N. Y., Painted Post, N. Y., 34th St., New York City, and Sherbrooke, Quebec. They will be operated. The officers of the Ingersoll-Rand Co. are: President, W. L. Saunders, formerly president of the Ingersoll-Sergeant Drill Co.; 1st vice-president, George Doubleday, formerly treasurer of the Ingersoll-Sergeant Drill Co.; vice-presidents, Jasper R. Rand, formerly president Rand Drill Co.; John A. McCall, president New York Life Insurance Co.; J. P. Grace, vice-president of W. R. Grace & Co.; Geo. R. Elder, general manager manufacturing department; treasurer, W. R. Grace, formerly secretary Ingersoll-Sergeant Drill Co.; secretary, F. A. Brainerd, formerly treasurer Rand Drill Co. For the present the main offices of the new company will be at 26 Cortlandt St., New York City.

## Trade Treatises.

The Holderman filter tank cyanide method is described in a trade treatise from the company, whose office is 16-23 Commercial Club annex, Salt Lake City, Utah.

Lighting generators, alternating and direct current, receive suitable attention in a literary gem from the Crocker-Wheeler Co., Ampere, N. J., whose Denver, Colo., office is at 525 Seventeenth street, and San Francisco, Cal., office is corner Fremont and Howard streets.

The standard size (9x12 inches) catalogue of the Wellman-Seaver-Morgan Co., Cleveland, Ohio, is devoted to ore and coal handling machinery. There is a series of full page engravings, showing the equipment of the company's manufacturing plant, similar fine portraits of labor-saving ore unloaders in use at various places, and technical explanation of the efficiency and practical working of those machines. The economy and general advantages of the machines shown are graphically portrayed. The book is finely produced and is worthy of a place in any mining engineer's office.

## Latest Market Reports.

SAN FRANCISCO, June 23, 1905.

### METALS

SILVER.—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, bar silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 47c, San Francisco; 45½c, New York.

COPPER.—New York: Standard, \$15.00; Lake, 1 to 3 casks, \$15.00@15.25; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.25@14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £66 2s spot per ton.

Copper prices show a slight advance in New York and London. It is estimated the exports for June will reach 20,000 tons, of which 3000 tons go to China. The supply and demand are seemingly well balanced at present and no material change either way need be anticipated in the near future. The total visible supply June 1 was 17,227 tons.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: 413 ½ long ton.

SPELTER.—New York, \$5.35; St. Louis, \$5.70; London, £24 ½ ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.60; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 3½c, 35@37½c. London, £139 5s.

PLATINUM.—San Francisco, crude, \$18.50 ½ oz.; New York, ingot, \$19.50 ½ Troy oz. Platinum ware, 75@82c ½ gram.

QUICKSILVER.—New York, \$39.00@40.00, large lots; London, 47 7s 6d; San Francisco, local, \$38.00@38.00 ½ flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.75c; San Francisco, Plumbers', 100-lb. lots, 17.50c.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., 40c.

NICKEL.—New York, 55@60c ½ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ½ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$15.60; gray forge, \$16.00; San Francisco, bar, 3c ½ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00@23.00; open heart billets, \$23.00@23.00; San Francisco, bar, 7c to 12c ½ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7½c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, 1c ½ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city ½ bbl.

CEMENT.—Imported, \$2.15@2.65 ½ bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 ½ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; latb, 4 feet, \$4.50@5.00; pickets, \$21.00@25.00; shingles, \$2.50 for No. 1, and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Walsend, \$7.50; Brymbo, \$7.50; Pennsylvania, bd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ½ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ½ lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 ½ 100 lbs.; byosulphate of soda, 3@3½c ½ lb.; caustic soda, in drums, 3@3½c ½ lb.; Cal. s. soda, bbls., \$1.10@1.20 ½ 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c ½ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c ½ lb.; nitric acid, carboys, 8c ½ lb.

OILS.—Lined, hoiled, hbl., 62c; cs., 67c; raw, hbl., 60c; cs., 65c; Lucol oil, hoiled, hbl., 54c; cs., 59c; raw hbl., 52c; cs., 57c. Kerosene—Pearl, per gal., 17½c; Asral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal,

iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 36° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Blonched, do., 57c; Whale Oil, cs., 52@67c.

BORAX.—Concentrated, 6@7c ½ lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ½ lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ½ lb.

MOLYBDENUM.—Best, \$2.75 ½ lb.

CHROMIUM.—90% and over, ½ lb., 80c.

URANIUM.—Oxide, ½ lb., \$3.50.

MERCURY.—Bichloride, ½ lb., 77c.

TUNGSTEN.—Best, ½ lb., \$1.25.

PHOSPHORUS.—American, ½ lb., 70c.

SODIUM.—Metal, ½ lb., 50c.

BISMUTH.—Subnitrate, ½ lb., \$2.10.

SILVER.—Chloride, ½ oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ½ lb. 7½c; less than 500 lbs., 8c.

MANGANESE.—Black oxide, ½ lb., 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. h., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skowback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, 1000 lbs. in 125-lb. bngs, double, and dry ground, f. o. h., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JUNE 13, 1905.

792,245.—CAMERA—J. W. Anderson, Santa Cruz, Cal.  
792,394.—TUBE COATING MACHINE—A. W. Buchanan, Pasadena, Cal.  
792,250.—DREDGER—L. J. & W. F. Crawford, Hoquiam, Wash.  
792,505.—WATER ELEVATOR—Dolling & Wheeler, Richland, Or.  
792,122.—ELECTRIC SYSTEM—J. J. Pagan, San Francisco.  
792,153.—VIBRATOR MACHINE—P. B. House, Chatsworth, Cal.  
792,230.—EXPANSIBLE PULLEY—L. J. Johnson, Petaluma, Cal.  
792,331.—EXCAVATOR—C. & J. T. Kerr, Armada, Cal.  
792,423.—CAMERA—H. E. Kiessig, Sacramento, Cal.  
792,233.—FURNACE—J. W. Lansing, San Francisco.  
792,234.—WAVE MOTOR—G. M. Lynch, Los Angeles, Cal.  
792,541.—WEEDER—N. McEachern, Walla Walla, Wash.  
792,158.—DRILLING MACHINE—P. McKinnon, Berkeley, Cal.  
792,435.—LADDER—E. A. Meacham, Riverside, Cal.  
792,236.—SCISSORS—Melander & Jaquet, Tacoma, Wash.  
792,330.—BUTTER CUTTER—N. Menard, Los Angeles, Cal.  
792,061.—CRATE—Morley & Meate, Salem, Or.  
791,380.—DRILLING SYSTEM—A. Nelson, San Francisco.  
792,344.—CHECK—J. W. T. Olan, Seattle, Wash.  
792,458.—WOOD PRESERVATIVE—R. P. Reynolds, Walla Walla, Wash.  
792,242.—CAN—P. S. Teller, San Francisco.  
792,371.—HOLDBACK—A. P. Weeks, Santa Cruz, Cal.  
792,372.—ENGINE VALVE GEAR—J. L. Wheeler, San Francisco.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

CONCENTRATOR ATTACHMENT.—No. 791,711, June 6, 1905, Frank S. Morgan, Nevada City, Cal. This invention relates to a device which is especially designed for use in conjunction with concentrators for the purpose of saving gold and amalgam and separating these valuable substances from slimes and sulphurets with which they may be associated. It consists of the combination with an endless traveling concentrator belt and the oscillating frame thereof, of standards fixed to and rising above the frame, an amalgamated plate supported upon said standards and inclined downwardly toward the head end of the belt, distributing boxes at both ends of the plate, means adapted to deliver pulp directly from a battery or feeder into the distributing box at the higher end of the plate, means for imparting a transverse oscillation to the frame and plate, and means within the lower distributing box to separate the free gold and amalgam as they flow with the pulp from the feeder to the belt.

DECORATING MACHINE.—No. 791,681, June 6, 1905, Henry T. Epperson, San Francisco, Cal. This invention relates to a machine which is designed for decorating china, glass, and ceramics generally, both over and under glaze, but is particularly adapted for under-glaze work. Its object is to overcome the difficulties of previous methods and to provide a rapid and accurate decoration of such articles as the machine is applicable to and which can be operated by inexperienced operators. The device comprises means for decorating articles, said means including a revolvable pattern carrying disk, a color distributing roller, adapted to be rotated by contact with the disk, means whereby the roller is advanced continuously in one direction simultaneously with its rotation, and means whereby the roller at the completion of its advanced movement may be moved out of contact with the disk and returned to initial position without contacting with said disk.

EXPANSIBLE PULLEY.—No. 792,230, June 13, 1905, Leune J. Johnson, Petaluma, Cal. This invention relates to an improvement in power-transmission devices wherein the driving pulley may be expanded or contracted in diameter and the driven pulley actuated by a driving chain, belt, or rope may be correspondingly contracted or expanded, so as to change the rate of speed. The device consists of an improved expansible pulley having in combination radially-disposed arms, a hub, and a shaft to which the hub was fixed, rims at the outer ends of the arms and in the plane of the outer faces thereof whereby the arms extend up along the inner faces of the rims to the periphery thereof, sections slidably fitting the inner faces of the arms and removable through the space at the top between adjacent rims and members within the sections and having projecting points at each end, said members being pivoted and tiltable within the blocks to present either point to engage with the power-transmitting chain.

CONTAINING CAN.—No. 792,242, June 13, 1905, Philip S. Teller, Alameda, Cal. This invention relates to improvements in containing cans; and it is especially applicable to cans which are designed to contain butter and like substances and a saline or other solution in which the contained substances must be continually submerged. The device consists of a can having a sheet-metal body of substantially even diameter, and having the top formed with a divergent upwardly-extending flange, a top having a dome-shaped centrally-located chamber, a surrounding upwardly-divergent flange and an intermediate portion of the top adapted to form a shoulder or stop, said body containing a liquid preservative and a block of butter submerged therein, and said dome-shaped chamber adapted to retain a portion of the preservative above the butter, and said annular portion serving to prevent the butter rising into the chamber and to insure its being always submerged in the preservative.

METALLURGICAL FURNACE.—No. 792,233, June 13, 1905, Jacob W. Lansing, San Francisco, Cal. This invention relates to improvements in metallurgical furnaces, and particularly in furnaces employed for the treatment of telluride ores. In recent years many mines have been opened up and worked in which gold and other valuable exist in great quantities in combination with tellurium; but in order to extract these values it is necessary first to roast the ore. This roasting has generally been done in open furnaces, with the result that a considerable proportion of the values have passed off in the form of tellurium-fumes and have become entirely lost. The object of this invention is to employ a closed furnace and to provide means in conjunction therewith to collect and condense these otherwise lost tellurium-fumes and to save their values.
